CHAPTER XII.

THE LEGAL RIGHTS OF CHILDREN.[1]

(*a*) The growth of civilization and the reign of law, marked by the protection of children from unnatural parents—The patria potestas of the Roman—The interference of the Roman law to protect the orphan from the "familia"—The efforts of the early church to mitigate the right of the father to kill his child—The emancipation of the child at 21 among Anglo-Saxon communities suggested to have been nourished if not engendered by the feudal system, which made the serf or vassal swear fealty to the lord of the manor or district who then represented the State, and also to the complete absorption of the old religious functions of the pater familias by the new religious father or priest.

(*b*) The slum districts and their juvenile inhabitants—Their numbers—Nationality—Illiterate parents—Schooling—Employments—Dwelling places—The wages of the parents and the duration of enforced idleness.

(*c*) Decisions of the higher courts—The right of an individual not directly benefited to interfere with taxation for school purposes—The indissoluble unity of taxation and the illegality of attempts to segregate the body politic in classes differentiated by political or other opinion—The meaning of the term common or public school as distinguished from the meaning of any term used to designate a school which is "open and free to all," but not controlled by the State.

(*d*) Preliminary tabulation of the sources of income and the origin of the permanent school funds in the several States.

It is convenient, when discussing the status of facts which are in process of change, to invite a comprehension of the import of this change by attempting to show the true origin of the facts, or by assuming as true an origin which is, in reality, merely an historic possibility or hypothesis. Such an origin, whether true or assumed, is the point of reference which gives vitality to the argument, as the base line in surveying gives subsequent utility to the records of the survey.

As the primitive herds of human beings, it may be assumed, emerged from the promiscuity of savagery,[2] the organization of the family, both

[1] By Mr. Wellford Addis, specialist in the Bureau.

[2] Mr. McLennan's view in his "Patriarchal Theory," in which he opposes the "primitive" agnatistic theory, i. e., the patriarchal theory. See the criticism of his theory by Sir H. S. Maine, in Early Law and Custom, chap. VII.

in China and in Europe, appears in a form which in itself, though not in its antecedents, is susceptible of some degree of verification. Thus a very positive expression as to the total absence of legal rights of children is made in the Institutes of Justinian. "The power we Romans have over our children," say the compilers of the Institutes, "is peculiar to the citizens of Rome, for the men of no other nation have such control over children as we have over ours."[1] And again: "Our children who are begotten in lawful marriage are in our power" (in potestate nostra). In China, likewise, "Every person is in strict subjugation to somebody. The child is subject to his parents or guardian. They in turn are subject to their parents, and the grandparents may be called to account by the elders of the clan."[2] The patria potestas, the rule of the father, still exists in China, and with it a nation which passes in European literature for an illustration of a stable but an unimproving society. On the other hand, the patria potestas of the Roman in the hands of the Germanic and Celtic races of Europe has undergone and is undergoing fundamental changes; for the father, as a priest, owner, and judge is being entirely submerged in the conception of the parent as a protector or guardian influenced by natural affection and not by mercenary motives.

Originally, then, during the regal and republican periods of Rome, neither age, nor marriage, nor election to the highest public office, nor anything except emancipation terminated the power of the Roman pater familias over his son or his son's son, and the daughter passed on her wedding day into the power of her husband or his governor as though she, too, were a child. But the growing refinements of the age which welcomed Christianity in spite of the opposition of the government—the essence of government being conservatism—mitigated the terrors of the paternal power of life or death as gauged by the standard of the ethics of the twentieth century. The pagan Emperor Diocletian had forbidden the sale of children by their parents, but the first Christian Emperor, Constantine, struck the destroyer of his own child with the crime of infanticide. Further than that the law did not go, and it was only by the exertion and devotion of a new class of persons in the community—a class which had acquired the religious functions of the father of the Roman family, that is to say, the priests or religious fathers—that even so much as had been formerly ordained by Constantine could be realized.

What the pagan Roman emperors could not effect, owing to the impregnable organization of the Roman family of the regal, repub-

[2] When I was a Boy in China. Yon Phon Lee. Mr. Lee was one of 120 boys sent by his Government to be educated in America, after a preparatory course in China.

lican, and early imperial epochs, was nevertheless put in process of change for future civilizations by that rationalizing machine called the Roman law. During the times of the so-called kings of Rome, when the father died, his children—under the age of 15 if boys, and of 12 if girls—were placed in the hands of the nearest male relative as a matter of personal right.[1] In those early times the state had nothing to do with this substitution of the relative for the deceased parent. That was a right pertaining to the family (familia) organization, and it was the family that interposed between the parties concerned.[2] Other than this interference the ward or, as he was called, the "pupil" had no recourse against his guardian (tutor), just as formerly he had had none against his father.[3] But extension of business relations, warfare, and growing emancipation from the idea of the tribal organization probably made the interference of the council of family groups related by blood ineffective, and the law—that is, the state in its character of preventing injustice—took the matter in hand. First, the right of a particular kind of lawsuit, called "actio de distrahendis rationibus" (adjustment of accounts), was instituted as the form in which the ward might ask for an accounting from his guardian, and this was followed by the creation of another special action called "tutelæ" which seems to have been intended to supplement the suit for misuse of the ward's money (actio distrahendis rationibus) and to make the guardian responsible for letting his ward's property lie idle or otherwise neglecting his duty as tutor or guardian. The point is that in Roman law this actio directa tutelæ is separated from the general action or suit which may be made in every advanced system of law against trustees of any kind for their acts of omission as well as those of commission.[4]

Thus the State deliberately and, it may be added hesitatingly, interfered between the guardian and the ward and, through its judicial

---

[1] As long as the "primitive" family group held together it was under the guidance of the eldest male of the eldest line, and the amount of power possessed by this patriarch is shown to us in case of Roman heads of families. But the patriarch always tended to become merely a judge who decided causes in accordance with custom. So, likewise, his position as ruler of the family property changed, of which he began to be the steward rather than the owner. Starke, the Primitive Family, Aryan Peoples, p. 97; Sir H. S. Maine, Ancient Law; J. D. Mayne, Hindu Law and Usage, and W. E. Hearn, the Aryan Household.

[3] Cf. Sir H. S. Maine's dictum (Ancient Law, 3d Amer. ed., p. 155): "The guardianship of male orphans was no more designed originally to shield them till the arrival of years of discretion than the tutelage of women was intended to protect that sex against its own feebleness." The condition to which the later Roman law came is given below in the text, quoting Servius as quoted by Paulus.

[4] Cf. Kent's Comm., vol. 2, pp. 230-1, 13th ed., and De la protection des impuberes sui juris, dans l'ancien droit romain, par Paul Varnier.

officers or the judicial side of its administrative officers, indirectly laid the foundation of a far more social conception of parentage than the rigor of the pater-familias theory of the old city state allowed;[1] for this progress being made it was not difficult to apply to the father Servius's definition of guardianship, which may be stated as the power given by the civil law to protect a child who, on account of his age, is not able to defend himself. (Vis ac potestas in capite libro ad tuendum eum, qui propter aetatem sua sponte se defendere nequit, juri civili data ac permissa.)

In speaking of the patria potestas in the foregoing no retrospective construction has been placed on the motives which actuated the so-called democracies, tyrannies, or respublicas of antiquity to leave the supreme power of life and death over offspring in the hands of the progenitor. It has been said that it was not the father, as a mere breeding animal, who was recognized by the Roman law as he in whom the patria potestas found a realization, but the father as the politically responsible part of the family. It has also been said that the main social idea of the society of Greece and of Rome was quite stoical, being a haughty preference for honor (virtus) while we moderns prefer comfort (utilitas). But it is doubtful whether either of these judgments upon antiquity find confirmation outside the classic pages of M. Fustel Coulange's[1] La Cité Antique and Plutarch's Lives and the like. The Memorabilia of Xenophon, Cicero's Letters, Horace's Epistles, and the Meditations of the Emperor Marcus Aurelius certainly impress the reader that he is being made acquainted with familiar characters as he turns over the pages of those writers who wrote candidly of their contemporaries or themselves, and the De Officiis was neither the handbook nor the model of Tiberius, Nero, or Sejanus, nor of the society they ruled.

The second blow to the Roman idea of the complete supremacy of

[1] La Cité Antique, by Monsieur Fustel de Coulanges, who has taken an advanced position among those who favor the patria potestas theory of the Roman society. If we turn to the condition of affairs among the pagan or pre-Muhammadan Arabians it is learned that, "Whatever amount of external protection this custom (the blood feud) may have afforded, it had no tendency to shield the women and children of a family against the male adults; the impulses of natural affection were too often unequally matched against the suggestions of avarice, lust, superstition, and false pride; and thus we find among the usages revealed to us through their subsequent condemnation the following: The plundering of male orphans by their brothers, uncles, or cousins, the general denial of rights of inheritance, if not all rights of property, to females, the enforced marriage of female orphans to their nearest male relative other than a brother, and of widows to the father, son, or brother of the deceased husband, or, as an alternative, their sale to a strange suitor, the sale of daughters in marriage, or in families where this had come to be thought disgraceful." (Rudiments of Law in pre-Islamite Arabia, by Sir R. K. Wilson in introduction to Anglo-Muhammadan (in India) Law, page 9.)

the father of the family was, in Europe, the loss of his function as the priest of the family. The third and most important one was the complete emancipation of the offspring on its attaining an age fixed by the state. Whence the idea of emancipation at the age of 21 came is unknown. It is thought to be Germanic in its origin, for the provinces of France that retained the Roman (i. e., the written law) preserved a remnant of the patria potestas while the provinces having the "customs" of their ancestors, or, as the English race say, common law, liberated the child on his becoming of age.[1] In France during the Revolution, the patria potestas was abolished after the child had become of age; but there is another side to it there, which is the duty of the parent to support the child. Even to-day, "in all but the poorest classes of the French people, marriage is made more difficult by inveterate family traditions. These center in a moral principle, which, perhaps, never existed in the Anglo-Saxon conscience. This tradition is that a parent is bound to protect and provide for his offspring through the whole course of his life."[2]

Be the matter as it may, there can be no error in turning to England, for there we find not only the common law and the feudal tenure built upon military service, which was due to a lord by the youth on reaching the age of 21, but also the earliest emancipation of the serfs or farm persons who cultivated the soil and intimately connected therewith the first direct interference with the right of the emancipated peasant or yeoman to neglect to make his child a decent member of society.

The reign of Henry VIII is memorable for the removal of mediæval restrictions. During its course some 2,500 religious houses were brutally but effectually eradicated, and nearly 100,000 dependents thereon thrown upon the country; the monopoly of the local conspiracies "to restrict the buying and selling of the goods" in each little city in which the guild merchant or one or more trade guilds dwelt was ruthlessly broken up; serfdom, already weak, collapsed under the new system of sheep farming, and the country was filled with beggars.[3] In short,

[1] From the Jus feudale Allemanicum (and Schwäbisches Lehensrechtsbuch) Cap 50. Tempus pubertatis est XIII annorum, et sex septimanarum a die nativitatis. Si Dominius minorem investiturus non aliter vult, tenentur agnati curatorem illi dare, qui respondit Domino nomine minoris in judicis feudali, et defendat ubi opus fuerit. Curator defendere debet minorem usque ad annum aetatis XXI et Domini ejusdem vassallus esse debet. (If the feudal lord does not otherwise determine as to a minor his agnates are held to appoint a curator to him, who is responsible in feudal law to the lord in the minor's name, and protects him, when necessary, until the age of 21 years. The curator must be a vassal of the same lord.

[2] Stoddard Dewey in Westminster Review, December, 1896. A daughter has always her "dot," and the French law recognizes the family council.

[3] They were then called sturdy [able-bodied] beggars; now they are called abnormal men.

by the confiscation of the monasteries alone, one-third of the wealth of England changed hands and the whole country was on a boom. Population, towns, commerce, and beggars rapidly increased.

In the twenty-seventh year of the reign of Henry VIII an act was passed which required that children between 5 and 13 found begging or idle should be bound apprentices to some handicraft. The apprenticeship law was compulsory upon master and servant alike; for the reception of an apprentice was not voluntary to the master.[1] This system has been called an education theory, and as such, says Mr. Froude, was simple but effective. "It was based on the single principle that next to the knowledge of a man's duty to God, and as a means toward doing that duty, the first condition of a worthy life was the ability to maintain it in independence. Varieties of inapplicable knowledge might be good but they were not essential; such knowledge might be left to the leisure of after years, or it might be dispensed with altogether without vital injury."

The children of those who could afford the small entrance fees were apprenticed to trades, the rest were apprenticed to agriculture, and if children were found growing up idle and their father or friends failed to prove that they were able to secure them an ultimate maintenance, the mayors in towns and the magistrates in the country had authority to take possession of such children and apprentice them as they saw fit, that when they grew up they might not be drawn by want or incapacity to dishonest courses.[2]

The origin of one part of the Puritan acts of 1642–7 is at once apparent. By those acts the selectmen of every town were directed by the legislature to do two things, one of which was to suffer no such barbarism as illiteracy. This part of the Puritan legislation was religious and original. But the selectmen were also instructed to see that all parents and masters "do breed and bring up their children and apprentices in some honest, lawful calling, labor, or employment, either in husbandry or some other trade profitable for themselves and the Commonwealth, if they will not or can not train them up in learning to fit them for higher employment." The originality of the Puritan laws therefore, consists in adding to the compulsory apprenticeship the obligation of parents to instruct their children in the fundamental branches of an English education in order to prevent, to quote the language of one act, "the snares of that old deluder, Satan." It will therefore be necessary to supplement Mr. Froude's laudation of the compulsory apprenticeship law drawn by Henry VIII with the

[1] State and Education, Henry Craik, M. A., LL. D., London, 1884. Also Froude History England, vol. 1, chap. 1.

[2] Such are the remarks of Mr. Froude on the "education of the poor" under the act of the twenty-seventh year of Henry VIII (Chap. XXV), Histy. England, vol. 1, p. 59. New York edition.

words of Mr. Webster in his Plymouth Rock oration: "We [the people of New England] regard education at public expense as a wise and liberal system of police by which property and life and the peace of society are secured and the whole moral atmosphere is purified."

Yet mere lawmaking will not accomplish results. Each one is very willing to have society interfere to protect himself from other people, but is impatient of social interference to prevent him from doing whatever he likes to others. Formerly the State in England issued its commands with astonishing frequency to local bodies to do this or that act of petty interference. The whole matter is now reversed. "We English," says Mr. Traill, "are infinitely more governed though less legislated at than our ancestors. It seems proper that the State—the government by the people—should not wish to be ridiculous by merely commanding the citizen to do certain things, but should see that he does it, and our English legislators are continually acting or being solicited to act on the assumption that it is their duty to take care of the public intelligence and the public health."[1]

The conception of the introduction and social effects of an epidemic of cholera or yellow fever is sufficiently vivid as not to require illustration, but the manner of introducing an idea into society and its effect is not so apparent. To explain this process Mr. Tarde has rejuvenated the association of ideas theory in the guise of the laws of imitation[2] or propagation of an idea through the crowd, and it seems important to dwell upon his exposition, though merely the scientific statement of what every politician and cultured person knows.

In his book Mr. Tarde calls his work a study in sociology, and properly so; for it is with society that he is dealing. He is not concerned with the psychology of the individual as such, but with the psychology of the individual as a member of society. This is the fundamental presupposition of the whole book; for it is evident that there can be no imitation in a society composed of a single person. The work is therefore an essay on what the Germans Lazarus and Steinthal called Völkerpsychologie, as it treats of the effects arising from a large body of persons holding in common one language and the same ideas. Society, according to M. Tarde, is an organism made up not

[1] Central government. It is to be added that the State and Federal powers assured by the Constitution make the use of the word "state" a little ambiguous in this connection, unless it be remembered that all the powers not granted to Congress are reserved to the States, and that the Supreme Court settles disputed cases.

[2] Les lois de l'imitation, étude sociologique, par G. Tarde, Paris, 1890; also, La logique sociale, 1896. In addition, there are many works of the same nature: Dumont's De population et civilization; Le Bon's Evolution psychologique des peuples and Psychologie des foules (Psychology of the crowd); Lacombe, Histoire comme science, etc.

of similar molecules as is the atmosphere, nor of similar cells as are living bodies, but is an organism made up of similar ideas which have been disseminated among the crowd by a process which in its psychological aspect may be called imitation, and in its physical may be called repetition. This process of imitation or repetition is analogous to other processes in the universe, to name them: The vibration of the ether which results in the phenomena of light and sound, the transmission of the characteristics of the progenitor in the process called heredity, and even the spread of a disease such as the epidemic called the black death during the Middle Ages. Firmly fixed, this conception of a society as a self-conservating spiritual organism soon disposes of the Aristotelian idea of a division of labor and the social contract and the communistic ideas. Society is not a thing of to-day, not a conscious convention of its members, not an exchange of mutual services, but a nexus of ideas similarly held into which new ideas are being constantly injected by invention and disseminated by imitation, or, to say the same thing in other words, by being repeated over and over again in each one of a multitude of units. This manner of regarding society as a body of similar ideas gives it a mechanical cast. For in order to change society (that is to say, a body of similar ideas held by a multitude) a sufficient time must elapse before the new ideas necessary to produce the change can be sufficiently disseminated to be effective. Thus every law passed by a State runs the risk of making but feeble inroad upon the body of ideas held by the people if some general interest or danger does not promote its observance; but it must be noted that under the press of successful revolution or of apprehension of great and immediate evil, reforms go to extremes and presage anarchy, Cæsarism, and a new society.

Before proceeding to examine the efforts made in England and elsewhere in the line of introducing new ideas as to the employment and education of children, it is advisable to state the conditions under which such interference by the State is thought to be necessary. Let us therefore examine the—

II: SOCIAL ENVIRONMENT OF CHILDREN IN THE SLUMS OF CITIES.[1]

There is no subject upon which it is so easy to be sentimental as the reformation of the depraved. It is a topic which never wearies the reader, and therefore one particularly dangerous to the writer. In the following exposition the social conditions of the actually depraved and, so to speak, merely degraded poor will be presented statistically and then the figures commented on as briefly as is consistent with an attempt to point their meaning.

[1] The statistics of this section are, though somewhat rearranged and recomputed taken from the elaborate work of the Hon. Carroll D. Wright, U. S. Commissioner of Labor, being obtained by his specialists in pursuance of an act of Congress.

In the four great cities below mentioned the census takers of 1890 and the special investigators of the United States Department of Labor in 1893 found the following facts:

1.—*Population.*

City.	Of cities, 1890.	Of slums (estimated).	Of special slum district examined in 1890 and 1893.	
			1890.	1893.
Baltimore	434,439	25,000	16,878	*a* 18,048
Chicago	1,099,850	162,000	17,637	*b* 19,748
New York	1,515,301	300,000	27,462	28,996
Philadelphia	1,046,964	35,000	15,409	17,060
Total	4,096,554	582,000	77,386	83,852

a Three per cent were negroes. *b* Four per cent were negroes.

Here are four millions of people, many more than the Republic contained when the Constitution was adopted with its preamble beginning, "We, the people of the United States, in order to form a more perfect union, establish justice, and insure domestic tranquillity," etc. Among these four millions of city dwellers are found 14 persons in every 100 separated socially from the other 86 by characteristics sufficiently obvious to entitle the section in which they dwell to a distinctive name, "the slums," just as the congregation of moneyed persons is called the "west end," and the like. A certain portion of these slums in the four cities combined increased its population during a period of three years to the figure of 8 per cent, so that the slums are not decreasing. The question is immediately suggested, Are these people Americans? Have they had the advantages of the public schools? Let us see.

2.—*Nativity (of slum districts examined in 1893).*

City.	Population of slum district (1893).		Population of whole city (1890).	
	Born in United States.	Born outside United States.	Born in United States.	Born outside United States.
In every 100 persons there were in—				
Baltimore	59.79	40.21	84.12	15.88
Chicago	42.49	57.51	59.02	40.98
New York	37.42	62.58	57.77	42.23
Philadelphia	39.55	60.45	74.26	25.75

That the population of the slums is largely a product of immigration there can be no doubt. Sixteen persons in every 100 of the population of Baltimore are immigrants, but over 40 persons, almost three times as many, in every 100 in the slum district are immigrants. Nor is this a full expression of the contribution of the immigrant

population to the slum district, as their children born upon American soil are counted as Americans. Having found that the immigrant population furnishes possibly as much as two-thirds of the slum population of a certain typical district of each of the three largest cities of the United States, we may now examine into the literary attainments of the population over 10 years of age.

3.—*Illiteracy (number above 10 years of age unable to read and write in any language living in slum districts examined).*

Illiterates.	Baltimore.		Chicago.		New York.		Philadelphia.

a Three per cent of the slum population are negroes.
b Four per cent of slum population are negroes.

It is quite apparent that one-fourth to one-half of the immigrant population can not read or write even in their mother tongue. It is also evident that illiteracy is, in the slum districts of the three larger cities, six or seven times greater than in the whole city, including, of course, all the slums. Certain statistical refinements might be made upon this table, but as the object here is merely to show the social condition of the slums in its grand lines we pass to the consideration of the schooling received by—

4.—*Children 5 to 14 years of age (16,803 all told, of whom 13,298 were of wholly immigrant parentage) for the four cities before considered.*

Total	3,983	c 23.7	1,108	6.6	11,544	68.7	168	.1	16,803	100

a Note that if this percentage had been written out it would have read: "In every 100 children whose parents were Americans (2,255 in all) 24.8 were kept at home." To take the percentage on the whole number of children 5 to 14 (16,803) would be unjust to the foreign population, or, to put it properly, inaccurate.

b This would read, if written out: "13.4 children in every 100 had American parents."

c This line of percentages has nothing to do with parentage, but in the case to which this footnote is applicable would read: "23.7 children of the 16,803 in the slum district of the four cities were kept at home;" and so for each following percentage.

It is quite clearly shown that the children of the slum districts go to school on arriving at the age of 6 or 7. Only six or seven children 5 to 14 in every 100 of the 16,803 children between those ages are at work, at least were so reported. The number of children kept at home, not counting the 11,122 under 5, is slightly in favor of the slum family having an American-born father, who in the city is the most indulgent father in this respect in the world, either through affection or neglect. But there is quite a difference between the American and the immigrant father in the other columns of the table, though in making this remark it is essential to add that 84 per cent of the 16,803 children spoken of in the table have immigrant fathers and only 16 per cent American fathers; for statistics is a science of large numbers, and numbers so small as 80 or 1,600 are rather inadequate for comparative purposes.

It might be expected that the general unhygienic conditions of the slums would cause a diminution in the size of the family living therein. That such is not the case is quite well shown by the following table:

5.—*Average size of family in slum districts.*

City.	Among slum population.	Whole population of city.
Baltimore	4.48	5.01
Chicago	5.09	4.99
New York	4.90	4.84
Philadelphia	5.15	5.10

It appears that the slums are more prolific in children than the whole city taken together. In Baltimore, in whose slum district the

native American population is one-half larger than the immigrant, the slum family is much smaller than the family for the whole city. In the four cities there were 11,122 children under 5 years of age born in the United States and 1,088 born abroad. In the same districts there were 10,484 children 5 to 14 born in the United States and 5,955 born abroad; in all, 29,013 children under 15 years of age. We may then divide the population of the slums examined in the four cities (83,852) into two bodies—those under and those above the age of puberty, respectively 29,013 and 54,839 persons. Thus it follows that there were nearly two persons 15 years or over for every child below that age. The daily home life and, in general, the environment of these 29,000 children is a matter of some importance, and we are led to consider another class of facts.

6.—*Pay, hours of labor, and period of enforced idleness of persons over 15 years engaged in remunerative occupations, as far as reported, during the year ending March, 1893.*

Sex.	Remuneration by week while employed.						Hours of labor a week.		Unemployed for three months.	
	Under $5.		$5 to $10.		$10 or more.		Selected number of workers reporting.	Average a week.	Number over 15 years of age.	Per cent of whole body reporting remuneration.
	Number.	Per cent.	Number.	Per cent.	Number.	Per cent.				
Men	2,177	9.2	11,403	48.2	10,060	42.6	a 24,823	a 61	9,905	32.5
Women	3,809	56	2,604	38.3	385	5.7	b 5,428	62		

a This figure does not include 2,238 workers not reported for the three classes of workers represented in the column: to wit: "Domestic and personal service," "trade and transportation," and "manufactures and mechanical industries." These three vocations, including the 2,238 from whom no report was obtained, give employment to 94 per cent of the male population of the slums.

b Not including 625 women workers not reported as to their hours of labor; 78.5 per cent of the women workers were following the vocations mentioned in note a above.

The workers of the slums have long hours, and if their daily task requires unremitting attention they are longer than modern ideas tolerate. It may be said, however, that of the three groups of vocations represented in the table—domestic and personal service, trade and transportation, and manufactures and mechanical industries—that manufacturing and mechanical shopwork are much the lowest in point of hours of labor providing Sunday be for each group a day of rest.

But the difficulty is that in every year one-third of the working population—at least one-third of the 30,438 who report their remuneration—are unemployed for three months or more. A merely living wage, together with instability of employment, is the microbe that, in an atmosphere saturated with illiteracy and indecency, breeds the city disease called slums, and the question is whether the ordinary amount and kind of education will suffice to overcome its effects

upon the infant character. The dwelling place, the home of the slum child, is susceptible of some degree of illustration by the following table:

7.—*Character of the slum home as shown by the amount of rent paid.*

By the week.	Baltimore.		Philadelphia.		Chicago.		New York.	
	Number such rents.	Per cent.	Number such rents.	Per cent.	Number such rents.	Per cent.	Number such rents.	Per cent.
Under $1	1,170	35.99	298	9.86	87	2.44	84	1.50
$1 to $2	1,342	41.28	1,123	37.17	1,247	34.91	2,036	36.47
$2 to $3	336	10.34	639	21.15	1,151	32.22	1,775	31.80
$3 to $4	171	5.26	308	10.20	428	11.98	994	17.81
Over $4	232	7.13	653	21.62	659	18.45	693	12.42

It will be noticed that the four cities may be separated into two classes according to the rents shown in the above table, namely, a class in which the slum population pay, in a large number of instances, a rent of under $2, and a class in which the larger number of rents paid is from $1 to $3.

Thus in Baltimore a little over three-fourths of the "homes" are rented for a figure under $2; in Chicago only a little over one-third are rented at those figures. Baltimore and Philadelphia are what may be called cheap cities. For instance, in Baltimore 13 per cent of the salaries (men) are under $5 and 50 per cent between $5 and $10, whereas in Chicago, the slum districts of which has a larger negro population than Baltimore, 5.5 per cent of the men receive wages under $5 a week and 42 per cent between $5 and $10. It is evident that more can be done with a dollar in procuring shelter of some kind in Baltimore than Chicago. But the question is, What is the duty of a dollar in affording its relative part toward maintaining its owner and his family in a respectable lodging? It is said that in Germany a man of small income ($200 or thereabout) will spend about one-sixth of it for his lodging; the proportion is said to be one-eighth; but, after all, the value of a dollar depends very much upon the character of the person who has it to spend.

The life of the slum dweller, then, is not so destitute of conveniences as the possible derivation of the word from asylum, or place of refuge for vagabonds and thieves, might indicate.[1] He is poor, and his work is intermittent; these are the great evils of his existence. He lacks the idea of permanency of every kind, save his empty stomach and pocket. He is off and on compelled to beg, starve, or to eke out enough from his poor wages while working to carry him through the time when he is unemployed. His reliance upon his own exertions is interfered with by intervals of enforced idleness, during which he is compelled to solicit employment like a beggar asking for alms, and which, as alms, is frequently given him. This tends to cause him to

[1] Cf. Scott's novel, The Fortunes of Nigel., The Alsatia, "both a grim and grimy place," the refuge for cutthroats, renegades, and the like.

feel like a slave, alternately to truckle and snarl. He becomes a peculiar kind of character in the body politic, upon which he floats at random, strong in body but weak in principles, especially the principle of conservatism, the champion of revolt and the client of the demagogue. It is evident that self-protection warrants a State in striving to prevent such barbarism that many thousands of children should be reared under these conditions.

III: THE OBLIGATION TO ATTEND SCHOOL; OR, COMPULSORY ATTENDANCE.

In the preceding matter of this chapter it has been assumed that the efforts of the Christian priests to break down the pagan practice of exposing children was successful, and now to the great reforming and protesting monk Martin Luther must be ascribed the first demand for compulsory attendance at school. "I consider the magistrate," he says, "bound to compel the citizens (burghers) to send their children to school; for if it is proper for the State to compel its citizens to take up arms in time of war, much more proper is it for her, both from a sense of right and duty, to make them send their children to school." Bugenhagen, the pastor of Wittenberg, went further. At the christening of the infant the father was sworn to instruct his children in the elements of learning. In short, the education of the people was a cardinal doctrine of the Protestant movement of the sixteenth century. Those who led it understood the "laws of imitation" as advanced by M. Tarde. The War of Thirty Years, those of Louis XIV, the Seven Years' War of Frederic of Prussia, and the Napoleonic wars put off the realization of compulsory education in Germany until 1817, when a department of public worship, medical affairs, and education was created. By this department a most comprehensive "entwurf" or bill was prepared, entitled "Allgemeinen Gesetzes über die Verfassung des Schulwesens im Preussischen Staate" (General provisions regarding the government of the school system of the states of Prussia). By this "all parents and guardians are obliged either to use the common public schools for the instruction of their children or wards or to provide them with an equally good means of obtaining such instruction." The Catholic bishops took a decided stand against the bill (as a whole), claiming that what the State had granted to them as an act of grace was not as much as the Catholic Church claimed as a right under the canon law, the platform of the Council of Trent,[1] the Peace of Westphalia,[2]

[1] A congress called to settle the questions threatening the disintegration of the Catholic Church, the procedure of which resembled that of a modern congress or parliament in which dicta are prepared by committees and then submitted to the whole house. Owing to the failure of the reformers to accept the promise of safe conduct, the body was composed of 187 Italian delegates, more than half.—Article Trent, Council of, in Catholic Dictionary, by Rev. W. E. Addis and Mr. Thomas Arnold.

[2] The treaty which put an end to the Thirty Years' Religious War.

and the decisions of the Imperial Deputies in 1803, by which all school matters were made causa ecclesiastica.

The bill never passed the stage of being a "sketch of a law," but compulsory education was steadily introduced by the power of Prussian bureaucratic government until its school system became so complete as to excite the wonder of Messrs. Guizot and Cousin[1] in 1833 and of Mr. Horace Mann several years later.

A powerful auxiliary and probably the necessary precursor of any compulsory school law is a law forbidding the complete monopolization of the years of childhood in labor for the benefit of the parent. In some cases this barbarism is, it is claimed, a necessity; but the recognition of such necessity gives rise to a cloud of spurious cases. The civil law embodied in the Code Napoleon compels the parent to support the child, and in several American States the statutes have laid down the same rule. Under such circumstances the head of the family as a political person is not apt to be so hostile to having the child educated, even though he regard the child as a mere encumbrance naturally following the gratification of his sexual instincts. In 1839 the Prussian Government forbid the employment of children under 9 years of age in any factory or mining establishment, nor might any person under 16 years who had not attended school three years or more and who could not read or write be so employed. It is quite possible to believe that there is no illiteracy in Germany.

In England it is necessary to make law in a different way. Not a public bureau, but public conscience must be aroused. In 1837 Mr. Dickens wrote his novel of Oliver Twist. There is a scene in that picturing the magistrates as refusing to indenture the boy, Twist, as a chimney sweep to a man plying that vocation. In 1840 there is also a "chimney sweepers and chimneys regulation act." By that act every indenture of apprenticeship to "any person using the trade or business of a chimney sweeper" is null and void if the child be under 16 years of age. In 1867 this was supplemented by the act with the bizarre title of "The agricultural gangs act," by which it is enacted that "whereas in certain counties in England certain persons known as gangmasters hire children, young persons, and women, with a view to contracting with farmers and others for the execution on their lands of various kinds of agricultural work. Be it enacted, (1) That no child under the age of 10 years shall be employed in any agricultural gang. (2) No females shall be employed in the same gang with males. (3) No female shall be employed in any gang under any licensed male gangmaster unless a female licensed to act as gangmaster

[1] Cousin's report is well known to American readers in translation by Miss Austin. The French law of 1833 carried through by the government of Guizot was the first for France. Napoleon and the mathematician Monge had laughed at Pastalozzi in 1803, when that worthy was a Swiss deputy at Paris. His system, as is well known, was eagerly caught at in Prussia after the downfall of Napoleon.

is also present with that gang;" and the justices were empowered to limit the distances within which the children were to travel on foot. In 1873 no child over 8 years of age could be employed in agricultural work unless proving that the child, if under 10, had attended school 250 times, and if over 10, had attended school 150 times, during the preceding year. In 1878 the factory and workshop act was passed, preventing the employment of children under 10 or on Sunday, and regulating the attendance at school of children legally employed in factories. In 1866 an industrial school act was passed, so comprehensive in its scope and minute in its details, and, withal, so controverted as an efficient machine that it must be passed with a mere reference.[1] By the "custody of children act," 1891, it is laid down that where the parent of a child applies to the high court or the court of sessions for a writ or order for the production of the child, and the court is of opinion that the parent has abandoned or deserted the child, or that he has otherwise so conducted himself that the court should refuse to enforce his right to the custody of the child, the court may, in its discretion, decline to issue the writ or make the order.

In France the civil code of the first Empire defined the power of the parents to be "a right founded upon nature and confirmed by the law which gives to the father and the mother, during a certain limited time and under certain conditions, the surveillance of the body (personne) and the administration and enjoyment of the property (biens) of their children. In 1875 a reconstruction of French society was begun by the Republic by attacking the gross ignorance and superstition of the peasantry and the fatal self-complacency of the provincial bourgeoisie and of the people who dwelt in the city of Paris. Free public schools, or "gratuité," compulsory attendance, or "obligation," nonsectarian teachers, or "laicité," and finally the loss of control of his child by the unworthy father, "La déchéance de la puissance paternelle," followed in regular order as fast as the Government found itself strong enough to cope with the opponents—royalists, imperialists, and sectarians—that its audacious plan of campaign encouraged to open resistance.

In the United States the enfranchisement of several millions of negroes gave rise to much examination of the question of illiteracy during the ratification of the fourteenth amendment to the Federal Constitution. Illiteracy had never been so frequent among the people of the Northern States as to create alarm. The situation in the new South was anxiously considered, and a national bureau was created to collect and disseminate information upon the topic of education. The census of 1870 opened up unpleasant vistas of popu-

[1] Some mention is made of these schools at page 426 of volume 1 of 1888-89 report of this Bureau. Several royal commissions have discussed their merits in voluminous reports.

lar ignorance which the census of 1880 defined. In the manufacturing States of the North a new danger menaced popular government. The growth of the factory system and the influx of illiterate foreigners called for resolute measures. The difficulty was magnified by the attempt to set up a rival system to the State at the expense of the State. At the present day State after State is adopting compulsory-attendance laws, which give great offense to those who see in such measures not the safety but the destruction of popular government and to those whose particular interests are not forwarded by such laws.

The compulsory school attendance laws have passed through one and have entered upon a second stage. In the earlier stage, each law was a mere brutum fulmen, incapable of anything save needlessly to create strife. A compulsory-attendance law requires two factors: Agents and seating capacity to carry it out. These desiderata seem to have been the cause of the failure of the early school laws, which were practically merely expressions of opinion as to what the local school bodies should do in the premises. In the other, or second stage, which is now coming into being, the laws are less bland, less general. A school is defined, the English language is to be taught, private schools are open to inspection as far as their attendance is concerned, officers are appointed to carry out the law, and the employment of children is regulated or forbidden. Much, therefore, depends upon the courts. A summary of their conclusions in the past is now given.

CONTRIBUTORY NEGLIGENCE ON THE PART OF THE STATE.

It was a maxim of the Roman law that each must bear the burden of his own faults (Quod quis ex culpa sua damnum sentit, non intelligitur damnum sentire).[1] This is morally true of States as well as legally true of men and corporations. The errors of the parents should not heedlessly be left to be visited upon a future citizen. For if in the organization of a State and the course of the industries it fosters opportunities are given for harm to happen to the child, the culpability of the State is that of the railroad corporation against whom it was decided by the Supreme Court of the United States that it had been guilty of contributory negligence in placing a machine in a place where children would probably resort to it and meddle with it, as the child injured had done. The brief of this decision reads as follows, quoting the court:[2]

1. While it is a general rule in regard to an adult that to entitle him to recover damages for an injury resulting from the fault or negligence of another he must himself have been free from fault, such is not the rule in regard to an infant of

[1] Digest 50, 27, De diversis regulis juris antiqui, par. 203, Pomponius ad Mucium.

[2] 17 Wall., 657. In the case of Gardner *vs.* Grace, an English nisi prius case, Mr. Baron (Justice) Channell probably first laid down this "dictum" against the "spirit of the decided cases."

tender years. The care and caution required of a child is according to his maturity and capacity only, and this is to be determined in each case by the circumstances of that case.

THE RIGHT OF THE STATE TO EXCULPATE ITSELF.

In the matter of Donohue et al., in New York, Mr. Justice Westbrook remarks:

The right of the State to care for its children has always and with very great propriety been exercised. Under its laws, whenever the welfare of the child has demanded, its courts have frequently interfered for the protection of children of tender years. It has again and again taken them from one parent and given them to the other, or has refused so to do, the good and the welfare of the child being the object always in view. It has so acted without the intervention of a jury, and that power has never been supposed to have been improperly exercised because a jury was not allowed and due process of law not had. If the courts of the State may, by virtue of their general powers, interfere for the protection and care of children, it is not seen why the legislature may not prescribe the cases in which children shall be rescued from their custodians and a mode provided for their summary disposition. For example, if children should be placed to learn the business of stealing, could not the legislature provide a summary remedy for the evil? Has the law no power to rescue summarily female children held for the purposes of prostitution or interfere in an expeditious manner in very many cases when children of tender years are exposed to peril or temptation? (*Cf.* the English act page 630.)

THE UNITY OF GENERAL OR PUBLIC LEGISLATION IN THE UNITED STATES.

In his Digest of Anglo-Muhammadan Law[1] Sir R. K. Wilson observes that a task such as his should have to be performed in England by an Englishman who has only once casually visited India is doubtless an anomaly, but it is accounted for, like so many others, by the one huge anomaly of the government of 250,000,000 Asiatics from the banks of the Thames. "'Mahommedan Law compiled from authorities in the original Arabic' by a descendant (Syed Ameer Ali) of the prophet and an ardent defender of the Moslem faith is, he continues, one thing, my 'Anglo-Muhammadan Law' quite another thing. For Mr. Ameer Ali, the eloquent author of The Spirit of Islam, to have made a perfectly colorless and pedantically accurate law book in his 'Mahommedan Law, compiled from authorities in the original Arabic,'[2] would have been little short of a miracle, and in his case the miracle has not happened. It is my business to direct attention simply and solely

[1] A Digest of Anglo-Muhammadan Law, setting forth in the form of a code, with full reference to modern and ancient authorities, the special rules now applicable to Muhammadans as such by the civil courts of British India, by Sir Roland Knyvet Wilson, Bart., M. A., LL. M., barrister at law, fourteen years a reader in Indian Law to the University of Cambridge. London, 1895, preface.

[2] The second edition, revised, appears to bear the title Mahommedan Law, by Hon. Syed (i. e., descendant of the Prophet Mahomet) Ameer Ali, C. J. E., barrister at law.

to what the British Government at the present time requires to be enforced as law for its Muhammadan subjects (about 40,000,000 of the 250,000,000), and for them alone." The necessary changes being made, Mr. Herbert Cowell, in the preface to his "The Hindu Law, as administered exclusively to Hindus (140,000,000) by the British courts in India," could have made exactly the same remarks as those just quoted from Sir Roland Wilson's preface and any Anglican writer who should attempt to digest what is meted out as law to the Buddhist subjects, of whom there are 3,000,000 owing nominal political allegiance to the Empress of India, might say the same. In short, while European law rests upon the people freely legislating to meet the demands of their own time, the Asiatic law rests upon ingenious commentations upon the utterances of holy men.[1] Any proposition, therefore, looking to the classification of children into sects by requiring a different set of officials, of tax lists, and a different method of treatment is a political evil that the Preamble of the Federal Constitution points as dangerous legislation. Efforts have been made, however, to make such distinctions as will appear from the matter now given:

In Louisiana a municipal corporation passed an ordinance allowing goods to be sold on Sunday by a number of citizens who believe, upon historical grounds, that Sunday comes on Saturday, while other citizens who believe that Sunday is the day of rest were prohibited from enjoying the privilege of keeping their stores open both on Saturday and Sunday: Held by the supreme court[2] to be partial legislation, and therefore unconstitutional.

In Kentucky, one of the States where the negro's aboriginal ignorance and century of involuntary servitude, together with the bitterness arising from a long and sanguinary conflict, made it desirable to educate that race apart from the Caucasian race, the Federal court held (1873) that a law was unconstitutional and void because it directed that the tax collected from white persons for support of public schools should be used exclusively for schools for that race and that the tax collected for colored persons should be reserved exclusively for schools for that race.[3] The supreme court of North Carolina, in Pruitt *v.* Commissioners of Gaston County (1886), took the same grounds.[4]

Indeed, this principle has been carried (leaving out of consideration its fundamental importance to a democracy) to an amusing length. In California, in the case of Lin Sing *v.* Washburn (20 Cal., 534), it was held that an ordinance of the city of San Francisco was void

because in requiring every inmate of the county jail to have his hair cut to within 1 inch of his scalp there was an intent to show dislike of Mongolian persons. In a Maryland case, where a police regulation declared that "no black Republican" should be employed by the police board, the supreme court of the State refused to take cognizance of such distinctions as being unworthy of notice, and in another State, where the affidavits of three "unconditional Union men" were required to remand a case of changed venue, the court disdainfully swept the distinction aside as invidious and therefore unconstitutional. In conclusion, it may be said that when for some physical characteristic or a peculiar belief a part of the community become notoriously segregated for a sufficient length of time, the isolated part or caste indubitably incur the dislike of the larger part of the community, and are only protected by the law and the respectful though sometimes distasteful obedience all true citizens accord it.

POWER OF THE STATE TO TAX FOR SCHOOL PURPOSES.

It is admitted, says Chief Justice Marshall, in one of those decisions which have put vitality into the idea of Federal Government both at home and in Europe, and causes the author to bear the same relations to the constitutional law of the United States that Lord Mansfield bore to the commercial law of England,[1] it is admitted that the power of taxing the people and their property is essential to the very existence of government, and may be legitimately exercised on the objects to which it is applicable to the utmost extent to which the Government may choose to carry it. The only security against the abuse of this power, he continues, is found in the structure of the Government itself. In imposing a tax the legislature acts upon its constituents. This is in general a sufficient security against erroneous and oppressive taxation.[2] The only consistent argument against this power of the State to tax a childless citizen for the education of other people's children is that of Mr. Herbert Spencer in his Coming Slavery. "English legislators," says the philosopher of the unknowable, "who in 1833 voted £20,000 a year to aid in building schoolhouses, never supposed that the step they then took would lead to forced contributions, local and general, now amounting to £6,000,000. They did not intend to establish the principle that A should be made responsible for educating B's offspring." The ready answer to which is that had they known as much in 1833 as they knew in 1885 they, as men over 21 years of age and competent to judge, probably would have begun with £6,000,000 instead of the grant of an amount that is bequeathed by half a dozen American testators to single institutions in the course

of a year; for a national education is a national drill, irrespective of the amount of the individual profit the cadet may derive from it, as has been remarked by the Puritan and Jesuit fathers and M. Tarde in his work on Imitation. National education may not make savants, but it softens the brutality of the asperities produced by failure or success through the operation of the most powerful and persistent lien in human nature, that of childhood recollections.

To what degree the State shall provide for the education of the people at public expense is a matter to be determined by the legislature, subject to such limitations as may have been introduced by the people of the several States in the State constitutions. An examination of these constitutions shows considerable variation in the provision made for education. The people of Pennsylvania in 1873 ordered their legislature to "provide for the maintenance and support of a thorough, efficient, and nonsectarian system of schools," and also to "appropriate not less than $1,000,000 annually for that purpose," while the people of Texas in 1876 ordered their legislature "to make suitable provision for the support and maintenance of an efficient system of public free nonsectarian schools," but in another part of the instrument, in limiting the right of the legislature to tax, they express themselves thus:

> The legislature shall not have the right to levy taxes or impose burdens upon the people, except to raise revenue sufficient for the economical administration of the government, in which may be included the following purposes: * * * The support of public schools, in which shall be included colleges and universities established by the State; and the maintenance and support of the Agricultural College of Texas.[1]

In default of judicial interpretation of the exact meaning of the provisions concerning education found in the constitutions of each of the States, as related to other parts of those instruments, it is necessary to refer to a compilation made in a former report of this Bureau.[1]

An early discussion in regard to the interpretation and meaning of the provisions of the constitution of the State of Pennsylvania is that of the Hon. Jeremiah S. Black, subsequently Attorney-General of the United States during Mr. Buchanan's Administration, while chief justice of the supreme court of Pennsylvania. That court, in 1851, was asked by one Hartman to be restored to the position of a school director in a certain district from which he and the other elected members of the board had been ousted by the court of quarter sessions of Lehigh County. These persons when elected had organized

[1] Documents illustrative of American Educational History, compiled and annotated by B. A. Hinsdale, Ph. D., LL. D., in Report 1892–93 of this Bureau. In Louisiana "The legislature can not force a parish [county] to levy a [local?] tax for school purposes" though "it may *authorize* it to do so," as the system of free public schools in Louisiana is a State institution, for which the State is required to provide by taxation or otherwise. 42 Ann.

themselves as a board and then refused both to establish the common schools required by the law under which they had been elected and to resign. The law (quite new) required schools to be established for "every individual 5 to 21 who cared to apply." The constitution only required the legislature to "provide schools throughout the State in such a manner that the poor may be taught gratis." Upon this very interesting and complicated issue the court said:

The whole ground on which this court has been urged to reverse the order of the quarter sessions is that the law is unconstitutional. We are of opinion that there is nothing in that law—certainly nothing in that part of it to which our attention has been particularly called—which in the slightest degree contravenes the constitution. It is to be remembered that the rule of interpretation for the State constitution differs totally from that which is applicable to the Constitution of the United States. The latter instrument must have a strict construction; the former a liberal one. * * * The powers not granted to the Government of the Union are withheld, but the State retains every attribute of authority which is not taken away. In applying this principle to the present case, it is enough to say that there is no syllable in the constitution of Pennsylvania which forbids the legislature to provide for a system of general education in any way which they in their own wisdom may think best. * * *

The constitution of Pennsylvania provides that "the legislature shall, as soon as conveniently may be, provide by law for the establishment of schools throughout the State in such a manner that the poor may be taught gratis. It seems to be believed that the last clause of this section is a limitation to the power of the legislature and that no law can be constitutional which looks to any other object than that of teaching the poor gratis. The error of these who make this argument consists in supposing this provision of the constitution to define the maximum of the legislative power, while in truth it only fixes the minimum. It enjoins them to do thus much, but does not forbid them to do more. If they stop short of that point, they fail in their duty; but it does not result from this that they have no authority to go beyond it.[1]

There is another interesting decision upon this point, though not in the proper sense a decision at law, but rather what in the Roman law might have been called a responsum prudentium.

On being requested, the supreme judicial court of Maine informed the house of representatives of the legislature of that State to this effect (abstract):

By the constitution of Maine (article 4) the legislature has "full power to make and establish all reasonable laws and regulations for the defense and benefit of the people of this State, not repugnant to this constitution nor to that of the United States." * * * Education being of benefit to the people and taxation being incidental to its successful promotion, a general tax for educational purposes must be constitutional unless forbidden or restricted by the constitution. The constitution, indeed, orders the legislature to require the towns to make, at their own expense, suitable provisions for the support and maintenance of public schools, but this is mandatory, not prohibitory.[2] (Cf. Black's decision above.)

Questions arise as to the power of the State to provide secondary and normal schools. A leading decision in this matter is that of Hon. Thomas M. Cooley, while one of the justices of the supreme court of

[1] Commonwealth v. Hartman, 17 Pa. (Dec., 1851).
[2] 68 Me., Appendix.

Michigan. In Stuart *v.* School District No. 1 of Kalamazoo (30 Mich.), it is laid down that school authorities in union school districts may levy taxes upon the general public for the support of high schools, and such taxation may be used for instruction in foreign languages, and that there is nothing in the educational State policy of Michigan or the State constitution restricting the primary school districts of the State in the branches of knowledge which their officers may cause to be taught or the grade of instruction that may be given, if the voters of the district consent, in regular form, to bear the expense and raise the tax for the purpose, or to prevent instruction in the classics and living modern languages in these schools.[1] Normal schools, as necessary to the full development of free schools, may be established by the legislature.[2]

THE SUZERAINTY OF THE STATE IN THE MANAGEMENT OF COMMON OR PUBLIC SCHOOLS.

Perhaps no more important decision touching the public character and hence the unity of the public schools has been made than that of the supreme judicial court of Massachusetts in the case of Rawson *v.* Spencer (1873). This issue, squarely stated, may be thus expressed: "Shall there be 1 or 1,834 or more centers of general educational control in the State of Massachusetts?" The opinion of the court was delivered by Mr. Justice Colt, and was directed and pointed by the following circumstances: The two laws of 1869 abolishing school districts in Massachusetts were contested by the original defendant as (1) confiscating property without just compensation, (2) as laying unequal taxes, and (3) as impairing the obligation of contracts,[3] upon which the court said:

> The laws in question were enacted in the legitimate exercise of that power by which the legislature may require the performance of certain public duties by different municipal agencies at its discretion. Before the enactment of these laws school districts were indeed quasi corporations, with the power to hold property, to raise money by taxation for the support of schools, and with certain defined public duties. But they were public and political as distinguished from private corporations, and their rights and powers were held at the will of the legislature, to be modified or abolished as public welfare might require. The laws in question do nothing more. They provide for the transfer of public property and of a public duty connected with its use from one public corporation to another. * * * There is no attempt to provide compensation in the sense in which compensation is required when private property is taken for public use under the right of eminent domain. The right here exercised is quite distinct from that and requires

[1] Richards *v.* Raymond (92 Ill.) is another decision to the same general effect.

[2] 4 Dillon.

[3] Under the laws of 1869, passed by the legislature of Massachusetts, the "Town of Uxbridge," a political division of that State containing several school districts, proceeded to take possession of all the property owned by such school districts, and to appraise the value of the same.

no provision for compensation. Nor do these laws authorize taxation which, under the bill of rights, must be regarded as not reasonable and proportional. The benefits to be enjoyed from public improvements and the use of public property can not be alike equal to all under any system. They are no more unequal under these laws than if districts had never existed or had not been abolished. The obligation of contracts is not impaired. Some of the districts may be in debt, but the rights of the creditors are in no way prejudiced. The taxpayers of the district are sufficiently protected by the assumption of all these debts by the town.

In an ingenious legal argument it was claimed in a Rhode Island case (St. Joseph's Church *v.* Assessors, 12 R. I.) that certain property belonging to that church but used for the purpose of maintaining a school free to all without charge was a public school and therefore not subject to taxation. The court would not entertain such a proposition and drew the distinction on the difference between free schools supported by the State for which it was answerable and the free schools of a system unfriendly to the State system and with which the State had very little if anything to do.

But though the judicial branch of the Government has steadfastly refused to allow the imperium of the State to be split up among the innumerable sects and faddists, which are inevitable in a government based on universal toleration and equality before the law, it is not to be understood that the personages whom the State calls into official being are thereby endowed with a temporary patent of dictatorship. Quite the contrary; it is Christian humility rather than pagan self-assertion that the courts require from public-school officers in the discharge of their duties. Nevertheless it must be confessed that the question turns on what is "reasonable." In a Wisconsin case (Morrow *v.* Wood, 35 Wis.) it appears from a case much complicated by the corporal punishment of a boy—now by the parent for studying what the rules of the school required, and now by the teacher for the boy's refusing to study what his father had punished him for studying—that a requirement to study geography is "unreasonable" if the parent in thinking so does not wish the authorities to introduce a new study for the parental benefit. On the other hand it has been laid down as "reasonable" that the power of the school committee to make all reasonable rules and regulations for the government, discipline, and management of public schools gave them the right to have the school opened with prayer and Bible reading notwithstanding certain parents claimed that these proceedings, during which their children are obliged to be at least physically present, are religious rites or ceremonies highly obnoxious to those parents for reasons satisfactory to themselves and their spiritual advisers. The first decision has been specially accepted as sound in an Illinois case (1877) and specifically repudiated (1879) as false in a New Hampshire case.

There are two great classes of these cases. One class is composed of those cases in which from some whimsical desire of the parent to

experiment or from some mental or moral bias an attempt is made to dislocate the routine of the schools by having this or that study of the established curriculum omitted for the parent's special benefit, while the other class is composed of cases in which it is attempted to have the atmosphere of the public school saturated as far as possible with the forms and usages of this or that particular creed. No general rule may be drawn from the cases decided except that in the North Atlantic States the courts have adhered to the idea of an undivided, impartial, and nonsectarian system of public schools in which no scholar is to be favored by the omission or addition of studies; for this would be practically, though indirectly, legalizing and supporting some particular kind of worship or some private business enterprise, as in the Wisconsin case above cited, where the father forbid the teacher to teach geography to his boy because he (the father) "wanted the boy to assist him to keep accounts."

NOTE A.—THE PRINCIPLE OF THE AMERICAN PUBLIC SCHOOL.

It is a propensity of the mind, as natural as it is frequently productive of error, to be guided by superficial resemblances. The more apparent these resemblances are, the more quickly an opinion is formed and the less inducement there is to seek or even to care for the deeper principles, though these, too, may lie quite near the surface, upon which the matter considered is based. For the American student of European education, considering such education as a department of government, a reflection of this kind is essential, for he must at the very outset of his investigations represent to himself the exact import of the term which M. Emile de Laveleye has used as a title to his book, L'instruction du Peuple. This instruction of the people has other names, such as popular instruction, but the common name given to it in the Latin countries of Europe is primary instruction, while in the Germanic parts of central Europe it is called Volkschulwesen, or the system of schools for the masses.

This species of education, or rather this education as applied to a specific portion of the population of a country, is intended for the common people or peasantry or lower orders, as the poor and uneducated inhabitants of the rural districts, especially, and the artisans and other wage earners of cities are invariably called. In Europe the original intention of modern attempts at educating these classes may be said to have been—paradoxical as it may appear—a reaction of at least one of the most humiliated monarchies of the Old World against the popular uprising known as the French Revolution, and the cry of emancipation raised by that revolution of "Liberty, fraternity, equality." But the appearance of paradox seems still more pronounced when it is considered that this very effort of a helpless monarchy to preserve itself from extinction should be apparently the same as that adopted by at least one republic in the new world to preserve its democratic institutions. Whether this indeed be a paradox merits investigation. A government is undoubtedly a government, whether in Europe or America, but a monarchy, though a government for the people, is neither a government by nor from the people.

Irrespective of the social status of the individual to whom given, the kind of education called in Europe "primary" or "popular" instruction has two characteristics which there distinguish it from all other systems of class education. The

first of these is that the schools are supported by taxation specifically laid upon the whole property of a community or a locality. The other characteristic is that such schools give instruction without cost to the pupil, except as far as his property or that of his parents or their labor is taxed to support the schools. These characteristics are in certain countries of Europe the outgrowth of a set purpose of their governments to strengthen the state by a process denominated national education, the keynote of which in Germany is the cry of Gott und Vaterland and in France is now La Patrie, though in the days of the French Revolution and the First Republic the cry was Liberté, Fraternité, Egalité, as before remarked.

The first system of national education was conceived and set on foot in the Kingdom of Prussia at the epoch of her greatest humiliation, during the Napoleonic wars. "We have hit upon the idea," says Stein, the head of Prussian political affairs, "that it is necessary to inspire the whole nation with a spirit of morality, of religion, and of patriotism." "We have lost a part of our territory," said the King, "and our renown as a nation is lost; but this is a reason why we should develop our intellectual power, and to this end I desire that everything shall be done to extend and render perfect the education of the people." It was the philosopher Fichte, however, who, in his addresses to the German people, first fostered the idea of a national as distinguished from a cosmopolitan idea of education. It is scarcely necessary to say that Fichte's scheme was preponderatingly ethical and national in character.

This "primary instruction" or "national education" is not regarded in Europe as in any way connected with culture. Mr. Matthew Arnold calls secondary instruction the first stage of a liberal education, and then goes on to say that Eton College (a secondary school), however defective otherwise, at least teaches her aristocratic pupils virtues which are among the best virtues of an aristocracy—freedom from affectation, manliness, a high spirit, and simplicity—and offers to her nonaristocratic pupils the benefits of contact with aristocracy, though at a too considerable outlay in money. Secondary education of this description is quite jealous, for the pupil is taken at a very early age by the authorities of the secondary school in which his education is to be effected, and whether in the "little college" of the French lycee or the progymnasium of the German gymnasium or in the lower forms of the English "public school" (Eton, Rugby, and the rest), he is carefully prepared for the liberal education of the secondary department proper of his school.

Such is the object of popular education as distinguished from aristocratic education in Europe. Turning to America, do we find the same conception of elementary education? There was a time during the first quarter of the present century when, inadvertently, through the anxiety of philanthropy rather than by premeditation, the people of the States of Pennsylvania, New Jersey, Maryland, Virginia, and South Carolina were classed as rich and poor. Mr. Hamilton, during his term as governor of South Carolina, is said to have expressed himself in regard to elementary public schools in the following terms: "The free-school system has failed. Its failure is owing to the fact that it does not suit our people, our government, or our institutions. The paupers for whose children it is intended need them at home to work." The same hostility of the native American "lower classes" to having their children marked as something of a lower order occurred in Pennsylvania, where the "poor-school system" was a most decided failure. Indeed, the principal motive that induces the parent to make sacrifices that his child may attend school is that it may become versed in the attainments that make

a lady or a gentleman. So widespread had this desire to be genteel become that to correct it some years ago a very determined effort was made to introduce into the public school curriculum instruction in the mechanic arts.

This, then, is the difference between the idea of the education of the masses of Europe and the idea prevailing in the education given by the public schools of the United States: In Europe the object is to absorb the individual in the contemplation of his duty to obey; in America the object is, to express the matter in the term used by one of our poets, Excelsior.[1]

[1] For the student of this phase of elementary and "high school" education, for they are inseparable in the United States, it is indispensable to familiarize himself with Theory of Education in the United States, prepared for the Vienna Exposition (Harris), and the article Etats Unis in Buisson's Dictionnaire de Pedagogie (Philbrick); for the administrative and financial side, the first section of the Report of the Committee of Twelve (Hinsdale); for the pedagogical side, the report of the subcommittee of five in the Report of the Committee of Fifteen (Harris), and also the Report of the Committee of Ten. A chapter published by this Bureau containing the provisions and expressions which occur in the constitution of each of the several States (Hinsdale) will serve as a sort of vade mecum in following the course of the education idea in the United States.

NOTE B.—*Tentative statement of the sources of revenue*

SECTION A.—STATE OR CENTRALIZED REVENUE, INCLUDING

Vested funds (or "permanent funds"), income only to be used.

Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
MAINE: Twenty townships of public school lands, the proceeds from the sale of those (and perhaps of other lands "assigned to towns for support of schools"), and the surplus of State taxation for school purposes form the permanent school fund, upon which the State pays 6 per cent, irrespective of the earnings of the fund.	Was given away per capita to local units, but $5,000 was set apart as a separate school fund, at 6 per cent, for the benefit of the territory then in dispute between the United States and the British Empire.	All surplus of the 1-mill State tax is added to "permanent school fund."
NEW HAMPSHIRE: None.....	The $700,000 received was distributed to the towns, some fifty of which seem to have kept the money, about $30,000, invested for school purposes, yielding about $1,800 annually.	None.....
VERMONT: None.....	Appropriated to towns for school or other purposes. The amount received was $669,087. The interest, at 6 per cent, was to be applied to support of schools. In 1885 it was found that "most of the towns apply the income to the support of schools."	The Huntington fund, amounting in 1892 to $212,000, upon which 6 per cent interest is paid. Vermont, it is said (Ann. Alm., 1846, p. 208, and 1847, p. 221) had a school fund; but it may have been merely an annual State appropriation.
MASSACHUSETTS: Sales of the Maine lands and subsequently one-half the proceeds of such sales.	The amount, $1,338,000, was given to towns. Of this sum about $25,000 were devoted by over one hundred towns to educational purposes.	The State permanent fund is made up of the proceeds of the sale of Maine lands, proceeds arising from the claims of the State on the United States for military service, war claims, and direct taxes. Refunding of Back Bay (Boston) lands and of the Western Railroad Corporation Stock. The fund is now nearly $4,000,000, and is increased annually by $100 000, until it reaches $5,000,000. The Todd fund of $12,000 is specifically for normal schools.
RHODE ISLAND: $4,276 received in 1858 from United States and was put to the credit of the United States surplus revenue.	The $382,000 received was originally devoted to education, and to it was added $4,276 from sale of public lands. The State borrowed all but $155,541, and then constituted that amount a permanent school fund, to which it subsequently added $11,192 surplus State revenue in 1860. The State pays no formal interest on this, which, at 6 per cent, would amount to $10,000.	None.....

for the support of public schools in each State.

AS SUCH TAXES LAID BY THE CENTRAL POWER.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
Tax on banks and one-half the tax on savings banks. Apparently the State normal schools are supported out of general revenue.	One mill on $1.....	None.
Taxes upon deposits, stock, accumulations of such depositors and stockholders of savings banks, trust companies, building and loan associations as do not reside in the State or whose residence is unknown shall constitute the literary fund. The surplus dog tax may be used for schools. Apparently the State normal schools are supported out of the general revenue.	The selectmen of each town are required to assess annually upon the polls and ratable real estate a tax to be computed at the rate of $500 for every dollar of the public taxes apportioned to that town.	See preceding column.
None. State normal schools, apparently, are supported out of general revenue.	Five cents on $1 of grand list (the poll tax and 1 per cent of the assessed value of real and personal property). The school districts shall annually assess not less than one-fifth nor more than one-half of the grand list.	
$100,000 is added annually to the permanent fund by act of June 16, 1894. By act of Apr. 11, 1895, $1,500 is given annually for an educational museum. County associations of teachers may draw $25 for every annual educational meeting. Apparently normal schools are supported by State from general revenue. Their buildings certainly are provided from general revenue. Up until 1895 the cost of such buildings has been $2,000,000.	.....	
Annual appropriation of $120,000 from out (1) the income of the permanent fund; (2) the general revenue, $3,100, is annually distributed to towns or districts for purchase of dictionaries, encyclopedias, maps, globes, etc., if districts raise double the sum they receive; an annual appropriation (amount not specified) for evening schools. The State Normal School is also apparently supported out of general revenue, as also the cost ($1,500) of transporting its pupils if they live 10 miles or more distant. $500 is appropriated for teachers' institutes and $300 for publishing educational literature. The surplus of the tax on dogs is to be used for school purposes, unless town or city otherwise determines.	None. (In every town there shall be kept for at least 6 months, etc., at the expense of the town, a sufficient number of schools in which, etc., etc. Cf. pp. 1088, 1089 of a Digest of School Laws published by this Bureau several years ago.)	$1 on voters (owning no taxable property), or so much of $1 as with their other tax shall amount to $1.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OR CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
CONNECTICUT: In 1733 the proceeds of the sale of "seven new townships" (one brought £6,800, another £1,225) in the colony were divided among the towns, as also in 1765 "certain sums due for excise on goods," the interest in both cases to be forever applied to the support of common schools. In relinquishing all claim to "Western lands" in 1782 Connecticut excepted the "Western reserve" as Georgia did the Indian lands within her borders (as related below), which, when sold in 1795, realized $1,200,000. By judicious investment this original sum had nearly doubled by 1840. The Western reserve contained 3,300,000 acres.	The amount received, $764,600, was deposited with towns, interest on one-half to be used for schools; interest on other half for ordinary local expenses. Practically three-fourths of the interest was used for schools until 1855, when the whole income was used for them. Some towns have wholly or partially lost the money.	None.
NEW YORK: In 1784 the "Stand lands" were laid off into blocks 10 miles square, subdivided into lots of 640 acres, one such lot in each block being reserved for promoting education and the gospel and another for promoting literature (1786). These formed the basis of the local school funds and of the State literary fund. Both funds received some increments by further land grants and the literary fund some for losses by grants in fee to specific institutions of "literary lots." The literary fund is now $284,201. In 1805 the common-school fund was established by the grant of 500,000 acres, the income from the proceeds of which was not to be distributed until the income reached $50,000. The fund is now $4,373,000.	The United States deposit fund is the original sum of $4,014,500. The "academies" get $30,000 for teachers' training classes and the school district libraries $55,000. The rest of the income apparently goes toward the payment of public-school teachers and some portion is added to the common-school fund.	None other than the increase of the common-school fund out of the "United States deposit fund."
NEW JERSEY: All money received from sale and rental of lands under water shall be a part of the permanent school fund.	The amount received, $764,671, was distributed among the counties as a trust. In 1867 the State required the whole income to be used for schools. In 1876 the income is $30,524. Probably there was not a county where the fund remained intact. Sixteen out of 21 counties set apart amounts equal to the interest that would have accrued if the fund had been at interest.	As a part of the permanent school fund shall be added as principal the interest of the bank or turnpike stock belonging to the fund, taxes on banking and insurance companies (after 1886), all appropriations made to fund, and all gifts.
PENNSYLVANIA: None	The $2,867,000 received was used for internal improvements to a large extent, though it is said that one-third of it was used to build up the school system then emerging from the "poor-school" régime.	None.

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
For every person 4 to 16 years of age the State gives $1.50 to each "town" or "district," apparently out of the general revenue. The State pays $2.25 for each evening-school pupil certified to the State comptroller; source whence money is derived not mentioned. State treasury honors orders of State board to the amount of $80,000 for support of normal schools; also $3,000 for teachers' institutes (both apparently out of general revenue).	None, except as given in preceding column.	None, except that the "poll" is not a head, but value which the State places at $100, apparently as a capitalization of the right of citizenship, which is thus taxed as property by the towns or districts at a specified rate per cent.
None. Normal schools are apparently supported out of common-school fund incomes. Buildings and sites are provided by community amid which school is placed.	Such tax as the legislature may annually determine. ("Free school fund.")	None as far as known.
The State normal school, the teachers' institutes, free libraries, State's share in supporting technical education, all come out of the income of permanent fund, but if there be a deficit, it is said that other money in the treasury may be used to cover it.	Tax of $5 on realty and personalty for each child 5 to 18.	None.
Persons found drunk upon the thoroughfares and public places are fined $2, which shall be turned over to the school district. The legislature is required to appropriate annually at least $1,000,000 for the public schools. The State does not directly support the Pennsylvania normal schools, but pays students intending to teach 50 cents a week and a bonus of $50 on graduation. The source whence this money is derived is not known.	There are three kinds of tax for school purposes, each separate and distinct, but all may be due from one person: (1) The rate tax on real and personal property; (2) the rate tax on such trades, occupations, professions, and salaries and emoluments of office as will yield over $1 by the rate on its valuation; (3) a minimum occupation tax of $1 on all resident male taxables over 21 years of age whose assessed occupation at the rate levied for school purposes will not produce $1. (School Laws, No. 1.)	None specifically as such; but item 3 in the preceding column is apparently such a tax, being really the former tax on "single freemen" (1857) who had no occupation or calling, including widowers as single freemen. The old form seems to bear upon celibacy and idleness.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
DELAWARE: None	The $286,751 received by the State was invested with the proviso that interest was to be used for support of schools. By judicious management the fund is now about $350,000, in bona fide values, convertible into cash.	None
MARYLAND: None	Amount, $955,838, appears to have been absorbed (indirectly) by unsuccessful schemes of internal improvements, but the State turned over stock in the "Baltimore and Washington Railroad" yielding $51,059 annually, which is reserved to the (permanent) free-school fund.	In 1858 the State received $173,559, principal and interest, from the United States for advances made during the war of 1812, which debt had been made in 1825 a part of the free-school fund. (There is some difficulty in stating just by whom the free-school fund of Maryland is held. Some of it seems to be in the hands of the State; another portion appears to be in the hands of the counties.)
VIRGINIA: None, except as mentioned in the third column, "unappropriated lands."	Not devoted to education	In 1809 this State originated the "literary fund" by setting aside all escheats, penalties, and forfeitures for the encouragement of learning. These accumulations were increased in 1816 by the war debt due from the United States. This fund supported the "pauper schools of Virginia," Mr. Jefferson's plan for a State system being set aside for an optional county system. In 1870 this fund was, nominally at least, $1,877,000.
WEST VIRGINIA: Unappropriated lands and lands sold for taxes or otherwise forfeited.	Nothing received	The State's share of the literary fund of Virginia (when received?), estates without heirs, taxes levied upon revenues of a corporation, exemptions from military duty, and such sums as may be appropriated and such property as may be given to the State without conditions.

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
Fees from marriage and tavern licenses, one-fourth of money derived from licensing auctioneers, foreign life-insurance agencies, the vending goods by samples, keeping traveling jacks or stallions, keeping eating house, taking photographs, acting as brokers, real-estate agency or exhibiting circuses, practicing jugglers, selling vinous, spirituous, or malt liquors, and one-fourth of fees on commissions issued to prothonotaries, clerks of the peace, recorders of deeds, clerks of orphans' courts, and sheriffs. Colored schools receive $9,000.	The school commissioners of each district must raise, without regard to vote of people, the following sums: In Kent County, $125; in Newcastle County, $150; in Sussex County, $75.	None.
Estates without heirs and escheats go to the county school board as coming from the State for school purposes. Normal school is supported from State tax. In 1812-13 a beginning was made in creating a free-school fund by taxing banks 20 cents on every $100 of capital stock. The war claims of 1812 and the surplus revenue (or its substitute, Baltimore and Ohio Railroad stock) were the other ingredients. It is doubtful if the 20-cent tax is still in force.	Tax of 10½ cents on $100 taxable property. This and the interest of the free-school fund are intended to pay teachers. See also second column of Section B for the contingency under which a tax is required.	None.
Escheats, forfeitures, fines for offenses against the State, and sale of unappropriated lands. Normal schools are supported out of general revenue.	Tax of 1 to 5 mills on the dollar.	$1 on each male 21 years of age.
See taxes levied upon corporations, etc., in preceding column. Normal schools are mainly supported out of general revenue.	10 cents on every $100 of real and personal property. Districts must levy a tax for building purposes not to exceed 40 cents on the $100 (which may be increased to 70 cents also if necessary to insure four months or other legal limit of school term), not more than 50 cents additional, and if a high school be kept, not less than 30 cents more, to provide buildings for and instruction in such high school.	$1 on every male of age.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	**Federal surplus revenue loan of 1836.**	**State accumulations "inviolably set apart."**
KENTUCKY: Some land was given for the purpose of education, but the proceeds were not devoted to an educational State fund.	Of the amount received, $1,433,754, $85,000 was "forever dedicated to public instruction," and was invested in "internal-improvement bonds." As the schemes of improvements were unfortunate, the State appears to have shouldered the debt and raised money to pay interest on it by taxation. See next column.	The 6 per cent interest on the bonds of Kentucky for $1,327,000; the dividends on 725 shares of the capital stock of the Bank of Kentucky ($73,500); $382,000 (accumulation of surplus of school revenue) due counties, at 6 per cent; $816,460 received from the United States Mar. 2, 1891; fines, forfeitures, and licenses in such proportion as the school tax bears to the whole State tax, excluding State school tax.
NORTH CAROLINA: In 1825 the proceeds from the sale of State and swamp lands, etc., and the unexpended balance of the agricultural fund were to be a part of the school fund. All proceeds from United States and swamp lands are now a part of that fund.	The $1,434,000 received was put mainly in the literary fund and probably was lost in the conflict of 1861-1865.	The sale of State and swamp lands, gifts and bequests of property for educational purposes, estrays, fines for breach of penal or military laws, and all the net proceeds of tax on retail liquor dealers and on auctioneers.
TENNESSEE: Congress gave one section in every township of public lands. In 1823 the State created a school fund by selling vacant lands and paid the money into the Bank of Tennessee, the school fund subsequently becoming a part of the capital of that bank, which part, in 1838, was limited to $1,500,000. The bank (a State institution) had a capital of $5,000,000, which was made up of the surplus revenue of 1836, the school fund, and additional sums to be borrowed. In 1865 the bank succumbed to the times.	The State received $1,433,758, but it was not apparently considered a part of the school fund, though some interest was used for education.	The State has issued a certificate of indebtedness for $1,500,000 and accumulated interest $1,012,500, upon which 6 per cent is annually paid. This is the permanent school fund.
SOUTH CAROLINA: None, as far known.	Devoted to general State purposes.	Land given by United States (if any), gifts for educational purposes, escheats, refunding of the direct-tax act of Congress, 1891, and the net assets or funds of all estates and copartnerships in the hands of the courts for seventy years, liquor licenses, except so much as is allotted to counties and municipal corporations (constitution, 1895).
GEORGIA: In 1783, 1,000 acres of land was voted to each county for the support of free schools, and in 1792 another 1,000 acres was granted to each county for a county academy. The State had reserved the right to the Indian lands within her borders when ceding her claims to the "Western lands" in 1782, the United States engaging to pay the Indians $1,200,000 for their lands.	The State received the $1,051,000 under protest, but added one-third of it to the "academic" and the "poor-school fund," both funds thereafter to be consolidated into the common-school fund. By the act of 1858, 6 per cent bonds for $350,000 were authorized and were issued during 1859 and 1860.	One-half the rental of the Western and Atlantic Rail road, liquor tax, show tax, Georgia Railroad stock, hire of convicts, fees of oil inspectors, poll tax, devices and gifts to the State, commutation tax for military service, all taxes on domestic animals as are harmful, lease of oyster beds.

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
See preceding column as regards fines, etc. The colored normal school receives $3,000 from general revenue.	22 cents on each $100 of real and personal property and corporate franchises.	For fuel and other necessities, a capitation tax of $1.50 shall be levied by district trustees on patrons of schools if the district falls short in school funds for that purpose.
See preceding column as regards fines.	18 cents on every $100 of property and credits. If this and the capitation tax is insufficient to maintain school four months, the county commissioners shall levy a special tax, but not if the State, county, and district reach the limit of 66⅔ cents on $100 and $2 on the poll.	State, 54 cents; county, not to exceed $1.44; together, not to exceed $2.
To the permanent school fund may be added the proceeds of escheated property and lands forfeited or sold for taxes, personal effects of persons without heirs, and unconditional donations. Normal schools are supported out of general revenue.	1½ mills on $1 of all property subject to taxation. In case of insufficient funds to maintain school for five months, the county court shall levy an additional tax for the purpose of maintaining schools for that length of time or submit to the people the proposition to vote a sum sufficient to maintain school for a longer period than five months.	$1 on every male of age.
Normal school supported from general revenue.	3 mills on the $1 shall be levied by the counties. But after 1898 a tax shall be levied by the general assembly to keep the schools open for a period to be named by that body. If the poll tax does not yield $3 for each child in the public schools during 1896-97-98, the comptroller-general shall levy a tax to make up the deficit (constitution).	$1 on males 21 to 60 years of age.
The taxes and funds inviolable set apart in preceding column. It appears that the legislature makes a lump appropriation ($900,000 in 1894), which is a part of the school fund. The State normal school is a part of the University of Georgia.	No specific State tax.....	$1 on each poll, if used for school purposes.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.

Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
FLORIDA: The sixteenth-section lands for public schools amounted to 968,503 acres. In 1882 there were reported as yet unsold 650,000 acres (under acts of May 20, 1826; June 15, 1844, and February 26, 1857) and a school fund of $326,420, invested mostly in State bonds. To this, one-fourth of the proceeds from the sale of public lands now or hereafter owned by the State.	None received.....	Unspecified donations to the State, escheated property, and forfeitures.
ALABAMA: 902,774 acres were received in 1819 for common schools (sixteenth-section lands). Capitalizing the interest received on this fund in 1875 at 6 per cent, the fund may be theoretically placed at $2,449,000. Many of these lands are leased by the "township superintendents" and are sold by vote of township. There is much litigation about title between State and claimants.	The $669,000 received was deposited in the State Bank, and in 1840 the interest was to form a part of the $200,000 required of the bank to establish a system of public schools. In 1848 "it was considered doubtful whether the university and school funds and the surplus revenue would ever be realized on," as the bank had failed. (Amn. Almanac, 1848.) See next column.	The State recognizes the interest due on the surplus revenue at 4 per cent; also that due on the proceeds of public-land sales at 6 per cent.
MISSISSIPPI: There were 817,534 acres of sixteenth-section lands. These were distributed to townships, who now hold a permanent fund of $197,421, from which, with rents, they derived in 1895 $26,890. The Chickasaw land fund is held by the State and amounts to $854,583, with 30,000 acres of land; interest, $51,000.	Not used for education.....	The rate of interest on the Chickasaw school and other trusts funds for education shall remain fixed at 6 per cent as long as they are held by the State.
LOUISIANA: There were 786,044 acres of sixteenth-section lands which were converted into bonds and were at the date of 1872, 834 State bonds of $1,000, 35 State bonds of $500, 272 city bonds of $1,000—in all, $1,123,500. It appears that these bonds were sold in 1872, and an investigating committee of 1878 uses the expression, "The abolishment of the free-school fund in 1872." The rent of school lands in 1894 amounted $5,070, and the interest on sixteenth-section fund to $44,000.	The $477,900 was three-fourths appropriated to pay State debt. The constitution of 1852 accepted the whole amount as a debt due to free-school fund.	The land granted by the United States—past or to come—the trust fund of 1836, estates of deceased persons without heirs, and all lands granted for educational purposes or without condition is a loan upon which the State pays 6 per cent interest.
MISSOURI: There were 985,000 acres of sixteenth-section lands. In 1892 the school fund was made up of $2,909,000 State certificates at 6 per cent, $231,000 at 5 per cent. In addition, there was a "permanent county public-school fund" of $3,783,539, a "permanent township public-school fund" of $3,370,369, and a "permanent district public-school fund" of $59,407. The proceeds from the sixteenth-section lands (permanent county public-school fund) seem to include the land sold for the benefit of the permanent township-school fund. Swamp land seems to have been given to the school fund, as the State board in 1879 was directed "to look into what the counties had done with them." These lands amounted to 3,300,000 acres.	The $382,335 were set apart for support of common schools, and the interest, at 6 per cent, was to accumulate until the amount became $500,000.	All money, stocks, bonds, lands, and other property belonging to any State fund for education, the net proceeds of the State tobacco warehouse, escheats, proceeds of public lands granted by Congress, and unconditioned gifts or bequests. The county permanent fund shall receive the proceeds of fines and forfeitures and exemptions from military duty.

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
The normal schools are, it is thought, supported out of general revenue.	1 mill on the $1, and every county is required to assess not less than 3 nor more than 5 mills.	None mandatory; but if levied by county, must be used for schools.
Escheats, licenses required to be paid into county school fund, $350,000 from general revenue, and $1,000 to be set apart for a contingent fund. State normals receive from $2,500 to $7,500 from State treasurer.	None specifically	Poll tax not less than $1.50.
A lump sum annually ($700,000 in 1895) to support schools four months. Normal schools are apparently supported out of general revenue.	do	Not to exceed $2 on all male persons 21 to 60 years of age. Such tax to be entirely devoted to support of public schools.
All fines by district courts and forfeited bonds in criminal cases (minus commissions), except parish of Orleans (New Orleans). Normal schools are apparently supported from general revenue. There is a corporation tax of $319,000 for educational purposes the exact functioning of which is unknown.	The legislature fixes (rate of) tax annually.	From $1 to $1.50 on males over 21. The tax is now $1.
Tobacco warehouse, etc., in preceding column. Not less than 25 per cent of the ordinary revenue of the State is set apart for public schools. Normal schools receive aid from State.	Not to exceed 40 cents on the $100 of valuation, except that in cities and towns it may be increased by vote to $1 on $100 and in districts to 65 cents. The amount may also be increased for building purposes, if two-thirds of the qualified voters so determine.	None.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
TEXAS: The Republic of Texas gave 17,713 acres (a Spanish league) to each county for "primary" and secondary education, which were not to be sold for twenty years. This, with other grants, gives a total of about 40,000,000 acres. In 1895 the leased lands yielded $177,438.	Nothing received.....	From $3,000,000 to $5,000,000 in bonds given in 1855–56. From these land and bond grants the permanent school fund amounts to about $22,000,000. This sum and about 17,500,000 acres of unsold school lands form the perpetual fund, which in 1895 yielded $1,295,377. This interest and such taxes as the State levies are the "available school fund," to which the legislature may add 1 per cent or less of the "permanent school fund." One-fourth of the occupation taxes is also added by the constitution to the fund for public schools.
ARKANSAS: The 886,460 acres of sixteenth-section lands were sold by each township, which then loaned the proceeds. The whole fund was broken up in the troublous times of the civil war. See for State lands in the third column of this heading.	The amount received, $286,751, was at first used generally. In 1842 the residue ($9,163) was made a part of the fund for public schools.	All money, stocks, bonds, lands, and other property now belonging to any fund for purposes of education, escheats, estrays, proceeds of sale of public lands given by Congress, 10 per cent of all State lands, also all grants, gifts, or devises to the State unconditionally, shall be preserved as a public fund called the common school fund.
OHIO: The 704,488 acres of sixteenth-section lands, 25,640 acres of swamp lands, 24,216 acres of salt-spring lands form a source of a fund upon which the State guarantees an interest of 6 per cent. The unsold lands of the sixteenth-section category produced, in 1895, $61,374 in the shape of rent. It appears that the sixteenth-section lands form a "common-school fund," and the salt-spring lands a "general fund," the first belongs to the township, while the second "belongs to the people of Ohio in common." (Law of March 2, 1831.)	The $2,007,000 was distributed to counties to be loaned to internal improvement companies, and the interest up to 5 per cent was to go to schools. Finally the act of March 24, 1851, added the "balance of the surplus-revenue fund" to the "common-school fund" (sixteenth-section lands).	In 1895 the income of the irreducible school fund was $251,569, of which $61,374 was farm rents of sixteenth section lands. The State guarantees 6 per cent on fund derived from land.

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
See preceding column for occupation taxes. State normals apparently supported by general revenue.	18 cents annually after 1805...	$1 on men 21 to 60 years of age.
None.....	Not more than 2 mills on the dollar.	$1 on men over 21 years.
None specified, but apparently a very large sum is annually derived from "fines, licenses, etc." The pedagogic department of the State University is supported from general revenue.	The legislature shall fix a rate of taxation at least once in every two years, and if in any year it fail to to do so it shall be 1 mill on the $1 of valuation. The proceeds shall be "The State common-school fund." Boards of education shall levy a tax not to exceed 3½ mills in cities of the first grade of the first class, and 1 mill additional for every 5,000 pupils over and above 25,000 enrolled in the public schools up to 7½ mills. In other districts the levy shall not exceed 7 mills. "In counties containing a city of the first grade of the first class, in districts outside such a city in which a high school is maintained, and in all special and village districts the levy shall not exceed 8 mills." This local tax, limited and required by the State, is called "contingent fund," and is used for continuing school after the State appropriation has been exhausted, and for buildings, textbooks, etc.	None.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
INDIANA: The 650,317 sixteenth-section acres received from the Congressional township fund, amounting to $2,502,000 in 1803, not including 196,600 acres unsold, yielding $35,208 in the shape of rent. The county auditor manages these funds. This fund was consolidated with the common-school fund in 1852, but was separated, as courts decided that the fund belonged particularly to the inhabitants of each Congressional township (36 square miles). In addition to the sixteenth-section lands 1,252,708 acres of swamp and 23,000 acres of salt lands have been received. The proceeds from the sale of these swamp and salt lands is given to the common-school fund.	The amount received was $990,254. Two-thirds was invested in internal improvements and one-third put in stock of State bank. The former part is supposed to have been lost. The bank stock, on the other hand, "eventually doubled." This would appear to be about $560,000, which became a part of the "school fund" which is held by counties, and amounts to $7,521,226.	The common-school fund is augmented by the bank-tax fund, the income from the State bank, fines assessed for breaches of the penal laws, all forfeitures, escheats, lands granted to the State unconditionally, and taxes laid on corporations for common-school purposes; also, surplus dog tax over $50 and liquor licenses.
ILLINOIS: There were received as sixteenth-section land 985,000 acres. The proceeds of these constitute the township fund, which now is $12,221,000, which earns 4.93 per cent interest. Three per cent of the proceeds of the sale of United States public lands in the State are also given, but one-sixth of this 3 per cent is set apart for higher education. Upon the proceeds of the 3 per cent given by the Federal Government the State pays 6 per cent and is called the school fund. It is now $613,362. There are 6,038 acres unsold school lands, whose value has been included in sixteenth-section lands above.	There were received $813,592, of which $478,000 were invested in internal improvements and $335,592 were placed in the school fund and then borrowed by the State and upon which it now pays 6 per cent interest.	None. There is a county fund of $158,617, giving an income of $9,000.
MICHIGAN: There were received as sixteenth-section lands 1,067,397 acres, yielding $3,834,357 (up to sales of 1892) at 7 per cent. The 5 per cent fund (one-half of 5,058,000 acres of swamp lands) amounted to $815,505 in 1892. The number of acres unsold is not known, but in 1876 there were 388,000 acres of sixteenth-section lands unsold held at $4 an acre. The salt lands that were given (25 out of 72 square miles) to the normal-school fund so far have yielded $99,656.	Devoted wholly to internal improvements.	Escheated lands are a part of the school fund. In 1891 the primary school fund at 7 per cent, consisting of the sixteenth-section lands and escheats, amounted to $3,803,203. The primary school fund at 5 per cent amounted to $838,104.

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
None. Apparently the State Normal School is supported from general revenue.	11 cents on the $100 of realty and personalty.	50 cents on each poll.
All fines, forfeitures (cities and incorporated towns exempted), laid by any court of record or justice of the peace shall be distributed by the county superintendent. This gave $23,257 in 1892. Apparently the normal schools are supported from general revenue.	2 mills on the dollar of valuation. Local authorities shall levy tax not to exceed 2 per cent for educational and 3 per cent for building purposes.	None.
Surplus dog tax if over $100. "The interest derived from the primary-school funds (5 and 7 per cent funds), together with the surplus of specific taxes remaining in the State treasury after paying the interest of the several educational funds and the interest and principal of the State department, forms the primary-school interest fund, the entire amount of which that may be on hand at the time is apportioned to the school districts of the State."—State Report, 1892, p. 45. The "specific taxes" above named appear to be taxes on corporations "laid by the constitution." In 1858 the surplus was $130,000 per annum. Both the specific taxes and the surplus now appear to be over $600,000.	For State appropriation see preceding column. The township supervisor shall assess 1 mill on the $1 of taxable property. There is a statement descriptive of the provisions regarding the amount of indebtedness that districts may incur for buildings, etc., by a two-thirds vote given in the Report of the Commissioner of Education, vol. 2, p. 1199, year 1893-94.	Do.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
WISCONSIN: There were received 958,049 acres of sixteenth-section lands, 500,000 acres public-improvement lands (act of Congress 1841), and the State's share of 5 per cent from the sale of United States lands within its borders, which last amounted to $455,254, all given to public school purposes. One-half of the swamp lands were given to the normal schools. (The swamp lands patented to Wisconsin up to 1880 were 3,071,458 acres) and form the so-called normal-school fund.	.....	Forfeitures and escheats, exemptions from military duty, and fines collected in the counties for breach of penal laws.
MINNESOTA: There were received 2,970,000 acres of sixteenth and thirty-sixth section lands, which in 1894 was valued at $10,712,120, having doubled in twelve years. An income of $360,700 is given.	.....	None.
IOWA: There were received as sixteenth-section lands 905,144 acres. In addition there were devoted to school purposes the 500,000 acres of internal-improvement lands and the 5 per cent of the sales of United States land in Iowa (amounting to $626,075 for schools). In 1895 the "permanent school fund" was $4,707,609, yielding an income of $235,663.	.....	Estates having no heirs.
KANSAS: There were received 2,801,806 acres, sixteenth and thirty-sixth sections lands. To the schools were also given the 500,000 acres of internal-improvement lands, the 5 per cent of the lands of the United States within the State as sold, and the 46,080 acres of salt lands; the last for normal schools. The State permanent school fund amounted to $6,166,389 in 1894, and the normal-school fund to $145,219. The interest on the permanent school fund was $346,634, and on the normal-school fund $41,050.	.....	Estates without heirs.

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
For institutes $6,000 may be taken from normal-school fund and $2,000 from "general fund," to which the State superintendent may add $1,000 from the "general fund."	1 mill on the $1 of valuation. The districts are limited in taxing themselves according to the number of pupils. See Report Commissioner Education, 1893-94, Digest School Laws, Wisconsin, Finances.	None.
Fines for breaches of penal laws not otherwise appropriated, liquor licenses, and estrays. The State supports normal schools and institutes. Any preparatory free school in a city or a village or a township organized on the township plan shall receive $400 from the State annually.	1 mill on the $1, to be known as the State school-tax fund, and the county commissioners (civil authority) shall levy another 1-mill tax, to be known as the local mill tax.	Do.
Exemptions from military duty; fines for breach of penal laws collected in counties. The teachers' institutes are partly supported from general revenue, as also the State normal school.	The county board of supervisors shall levy a tax for support of schools in county of not less than 1 nor more than 3 mills on the dollar. The district school board shall estimate (which estimate the county supervisor shall levy) the amount required for the contingent fund, not to exceed $3 a pupil; and for the teachers' fund an amount not to exceed, with semiannual apportionment of State money, the sum of $15 a pupil residing in district, and for schoolhouse purposes not to exceed 1 cent on the dollar. But the supervisors may levy $75 for contingent fund and $270 for teachers' fund, including, as before, the semiannual apportionment from State.	Do.
Exemptions from military duty and the proceeds of fines for breach of penal laws shall be applied in each county to support of common schools. Every insurance company shall pay $50 for support of the schools.	1 mill upon the dollar. Districts may vote a tax of not more than 2 per cent on the taxable property of the districts. Each high-school board shall estimate the amount required by it, and the county commissioners shall levy a tax not to exceed 6 mills on the dollar. Cities of the first class (15,000 or more) shall levy not more than 8 mills on the dollar where the assessed valuation is greater than $3,000,000; but in cities of 10,000 or more and in cities having a less valuation than $3,000,000 the board may levy as high as 10 mills.	Do.

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
NEBRASKA: There were received 2,702,044 acres of sixteenth and thirty-sixth sections. The superintendent says 2,782,098.72 acres have been acquired by United States grant, 288,126 acres have been sold, 582,754 acres are under contract of sale, 1,538,564 are under lease, and 372,665 acres still to be disposed of. The total income from the sixteenth and thirty-sixth sections lands seems to have been, in 1894, $57,256, which includes $109,444 interest on unpaid purchase money; $750,000 were in the treasury awaiting investment. The 5 per cent arising from sale of United States lands in State is now $116,579.	.....	All grants of lands or other property to State, if given without conditions. Escheats and forfeitures.
CALIFORNIA: There were received 6,719,324 acres of the sixteenth and thirty-sixth sections lands, to which was added 500,000 acres of the internal-improvement fund. The State school fund is $3,464,250, consisting of $1,526,530 in 6 per cent bonds and $1,937,750 in from 4 to 9 per cent bonds, also such per cent (5?) as Congress may allow State on sale of Federal lands within her borders.	.....	Estates without heirs.....
OREGON: There were received 3,329,706 acres of sixteenth and thirty sixth sections lands. The 500,000 acres of internal-improvement lands, 10 per cent of the swamp lands (i.e., 404 acres), and the 5 per cent on sales of Federal lands within the State ($34,911) were also given to common schools. The interest on the funds was, in 1894, $163,000.	.....	Escheats and forfeitures, exemptions from military duty, and property granted to the State unconditionally.
NEVADA: There were received 3,085,428 acres of sixteenth and thirty-sixth sections lands. The 500,000 acres of internal-improvement lands were given to education. So far as land has been sold, the proceeds are thus invested: (1) Irredeemable 5 per cent State bonds to the amount of $80,000 and (2) in United States and State 4 per cent bonds to amount of $591,000. In treasury there is $123,288 cash.	.....	Fines collected under State penal laws; 2 per cent of gross proceeds of toll roads and bridges; escheats.
COLORADO: There were received 3,715,555 acres of sixteenth and thirty-sixth sections lands. The fund now amounts to $1,229,000; approximate interest, $150,000. In the day of the Territorial organization a claim of 100 feet in length in each lode was vested in the common-school fund.	.....	Escheats.....

the support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
All fines, penalties, and licenses shall be paid to county school authorities, but such as are imposed by municipalities smaller than a county shall belong to such municipality as imposes them.	1½ mills on the dollar valuation on the grand list of th taxable property of the State. Districts shall not levy more than 25 mills in any one year, and 10 mills for purchase of schoolhouse, etc., but the aggregate amount shall not exceed 25 mills. In cities of 1,500 and more the tax shall not exceed 2 per cent, and in cities of over 25,000, 15 mills; but the board of education may borrow money on bonds.	None.
Normal schools are apparently supported out of general revenue. The State inaugurated a method of solving the textbook problem, granting in 1885 $35,000 for the compilation of such books and $315,000 for the purchase of machinery, etc., incidental to their publication.	The county superintendent in counties of less than 200,000 must calculate 1 teacher for every 70 census children or fraction not less than 20, and for each assumed teacher there must be raised $500; but there must be an amount equal to $6 for each census child in the county. The board of supervisors in counties of fewer than 100,000 must levy a tax (to be known as the county school tax) not to exceed 50 cents on $100 of valuation of property and not less than a minimum fixed by the law in a proportional way.	$2 on men 21 to 60.
None. State apparently supports normal schools.	The county courts are required to levy a tax per capita, persons 4 to 20, that shall at least equal the tax per capita of persons 4 to 20 in 1892.	None.
There shall be set apart semiannually 5 per cent of all moneys received as State tax for school purposes, to be distributed pro rata.	An ad valorem tax of one-half of 1 mill on the dollar. County commissioners shall levy county school tax from 15 to 50 cents on $100 of property. There shall be set apart for school purposes 5 per cent of all taxes.	Do.
Fines, penalties, and forfeitures; estrays.	County commissioners shall levy a tax of not less than 2 mills on the dollar of real and personal property nor more than 5 mills. There is a State tax of one-sixth of a mill for support of normal school. But see Section B.	Do.

NOTE B.—*Tentative statement of the sources of revenue for*

NOTE B.—*Tentative statement of the sources of revenue for*

SECTION A.—STATE OF CENTRALIZED REVENUE, INCLUDING AS

Vested funds (or "permanent funds"), income only to be used.		
Sale of public (originally mostly Federal) lands.	Federal surplus revenue loan of 1836.	State accumulations "inviolably set apart."
NORTH DAKOTA: There have been sold of sixteenth and thirty-sixth sections lands 130,474 acres for $2,310,053, of which sum a first payment of $462,000 has been made, the other portion being at interest at 6 per cent. The 5 per cent granted by United States of its sales of public lands brought in the sum of $5,408 in 1891-92, which was added to principal of vested fund, the interest of which and the rents, etc., of public lands form the "State tuition fund." Rent of school lands in 1894 netted $42,645; 80,000 acres additional were given for normal schools by the United States Government.	.....	Escheats .....
SOUTH DAKOTA: The sixteenth and thirty-sixth sections lands to be sold for not less than $10 an acre; 5 per cent of sale of land belonging to the United States; 80,000 acres are given to State normal schools. The two Dakotas, as a Territory, received 5,360,400 acres of sixteenth and thirty-sixth section lands.	.....	.....do.....
MONTANA: There were received of sixteenth and thirty-sixth sections lands 5,112,000 acres, which are to be sold for $10 or more an acre, 5 per cent of sales of public lands held by United States and 80,000 acres for normal schools.	.....	Escheats and forfeitures; grants not conditional to same purpose. Fund accumulating in treasury, proceeds of timber, stone, etc., from off school lands, except as otherwise provided.
WYOMING: There were received of sixteenth and thirty-sixth sections lands 3,480,281 acres. The percentage granted by Congress on sales of public lands held by United States.	.....	Escheats and forfeitures .....
IDAHO: There were received of sixteenth and thirty-sixth sections lands 3,068,321 acres. Apparently this has already produced a fund capable of yielding in 1893 $40,000, including, perhaps, the usual 5 per cent granted by Congress on sale of Federal lands within the State.	.....	Estates without heirs.....
WASHINGTON: 2,488,675 acres of sixteenth and thirty-sixth sections lands, which in 1894 gave an income of $77,800. Such per cent as Congress may grant (5?) of the sale of public lands held by people of United States within the State; 20,000 acres for normal schools.	.....	Escheats and forfeitures, grants not conditional to a specific purpose, funds accumulating in treasury otherwise unappropriated, proceeds of sale of timber and stone of school lands, except as granted for another purpose.
UTAH: No information.		

tne support of public schools in each State—Continued.

SUCH TAXES LAID BY THE CENTRAL POWER—Continued.

Statute funds at present converted to the use of school system or sums now annually voted from general revenue for support of public schools.	Specific State taxation for schools.	
	On property.	On polls.
None. Normal school partly supported from general revenue.	Each district shall levy a tax of not more than 30 mills on the dollar, and the county auditor shall levy a county tax of 2 mills on the dollar as a State tax.	$1 on each elector.
Fines for violating State laws. Normal schools apparently supported from general revenue.	County commissioners shall levy a tax of 2 mill on the dollar of taxable property. Districts are in general limited to 2 per cent, but not apparently required to raise anything.	Do.
All money arising from sale of town lots under laws of legislature to be paid into county treasury for benefit of school district in which lots are situated.	Optional	None.
Gifts not conditioned to a specific purpose. Fines and penalties under general laws of State.	Counties must levy a tax of not more than 3 mills on the dollar for all purposes.	$2 on each person 21 to 50.
Fines and forfeitures for breach of public laws.	County commissioners shall levy a tax of not less than 5 nor more than 10 mills on each dollar of taxable property.	None.
Fines, licenses, and estrays.....	County commissioners shall levy tax of not less than 8 mills on the dollar of assessed value taxable property. District boards may levy special tax not exceeding 5 mills unless voters consent, but no district tax shabll be over 10 mills. Cities of 10,000 are excluded from county taxation.	Do.

NOTE B.—*Tentative statement of the sources of revenue*

SECTION B.—LOCAL TAXATION

Kind of property taxed for local purposes.	Rate or limits of voluntary taxation.
MAINE: Not specified. Probably the same as for the State tax, i. e., "all property."	Not limited
NEW HAMPSHIRE: On polls and ratable real estate.	do
VERMONT: Grand list (the polls and 1 per cent of the assessed value of real and personal property).	One-fifth to one-half of grand list
MASSACHUSETTS: On property in the same manner as other town taxes are laid.	Such sum as the town deems necessary
RHODE ISLAND: Not specified	Such sum as the town judges necessary
CONNECTICUT: On real estate, ratable personal property, and manufacturing or mechanical business subject to taxation.	School visitors and selectmen fix the amount, but where towns have abolished district system amount is fixed in town meeting.
NEW YORK: "Taxable property," and in case of union free-school districts "all the real and personal property in the city or village taxable for defraying the expenses of its municipal government. The expression "taxable property" includes bank stock and railroad and telegraph property.	Not limited
NEW JERSEY: Real and personal property	Not limited
PENNSYLVANIA (see Section A under specific State taxation): District taxation is upon "all objects, persons, or property made taxable for State or county purposes, and shall be contained on the same blank."	Districts may tax themselves up to 13 mills
DELAWARE: When a school district has decided "for a tax," the assessment shall be made on polls (every freeman above 21 years is considered worth from $140 to $2,700 in addition to whatever property he may really own as a material fact; the tax on this is called a poll), on personal property of all white persons, and in the clear rental value of all the assessable real estate of white persons.	$400 for support of schools; $500 for building
MARYLAND: Taxable property	Should the State tax and income from "vested fund" prove insufficient to pay expenses of the schools of any county, the county school commissioners shall offhand impose a tax not greater than 10 cents on the $100, unless authorized to impose a higher rate by county (civil) commissioners.
VIRGINIA: Tax on property	10 cents on $100
WEST VIRGINIA: Real and personal property	Not to exceed 50 cents on $100 for school purposes, nor 40 cents for building purposes, but 70 cents if for a high school—in all, $1.20 on the $100.
KENTUCKY: Real and personal estate; corporate franchises directed to be assessed.	Not limited, except capitation tax. (See Section A and next column.)

for the support of public schools in each State—Continued.

(VOLUNTARY).

Conditions under which taxes not required by State (see Section A) may be laid, and for what purpose.	Conditions under which bonds may be issued, and for what purpose.
Voted at town meeting for general school purposes, including text-books. If a town support one or more high schools for ten weeks or more, it shall receive one-half the amount expended (but not to exceed $250) from the State.	Towns may raise money for establishing and maintaining free high schools and furnishing buildings and their appurtenances in the same manner as for supporting common schools and erecting schoolhouses.
Voted at town or school district, at legal meeting, for support of schools in the case of town tax; but in case of district tax, for purposes of procuring building and sites, planting ornamental trees, furniture, books, etc.	Majority of voters in district may hire money to build schoolhouse, but not to a greater amount than four-fifths of its cost.
Voted by district (at special meeting) for school purposes.	None, as far as known.
Voted by town for school purposes.....	Do.
Voted by town for maintaining schools, purchasing sites, erecting buildings and repair of same, and maintaining school libraries.	Do.
Voted as shown in preceding column; for the purpose of maintaining schools.	Do.
The common-school district meeting votes local taxes for purchasing sites and building houses, or renting, repairing, or furnishing them, including globes, maps, etc., for purchasing text-books and other supplies not to exceed $25 in any one year, for establishing a school library, for insuring buildings, paying teachers after State money has been exhausted, etc.	
Voters determine amount of tax at election of trustees of township for school purposes.	Legal voters by majority at meeting may authorize issue of bonds for sites, buildings, or repairs, at 6 per cent or less. An amount shall be levied each year to pay the principal and interest falling due in that year.
By vote of school directors or controllers for the purpose of keeping schools open from four to ten months in connection with the State apportionment. An amount not to exceed the regular annual tax.	School directors or controllers may borrow money at 6 per cent or less and issue bonds therefor in sums not less than $100, except in case the debt of the corporate body be already 7 per cent of the assessed value of its property.
Majority vote of district for support of schools or for building. (See preceding column for amounts.)	
See preceding column.....	
Levied by board of county commissioners for purposes of school district.	
District board shall levy the 50 cents on the $100 when it is necessary to enable the district to have four months' school or as many months as the voters have determined. This amount and that received from the State is called the teachers' fund.	District may bond itself, if it do not thereby raise its debt above 5 per cent of the value of its taxable property, provided also it be arranged at the same time that an annual direct tax to pay interest and redeem bonds in thirty-four years or fewer shall be levied.
Voters in a graded common-school district may raise 50 cents on $100 on property of white persons or a poll tax on each white male over 21, or both, for school purposes and buildings. In cities of the first class the maximum limit of taxation is 33 cents on $100, but in cities of the third and fourth classes the maximum is 50 cents. (See next column.)	To repair or provide schoolhouses and furniture the district trustees shall levy a capitation tax of $1 or less for four years on each (white) male of age or an ad valorem tax not exceeding 25 cents on the $100 of taxable.

NOTE B.—*Tentative statement of the sources of revenue*

SECTION B.—LOCAL TAXATION

Kind of property taxed for local purposes.	Rate or limits of voluntary taxation.
NORTH CAROLINA: Tax shall be collected on money, and shall be levied on all property, credits, and polls of the county.	(See Section A.) In case of special tax, 20 cents on $100 and 60 cents on the poll.
TENNESSEE: "All property subject to taxation for school purposes," and property, polls, and privileges.	Shall not exceed the State tax.
SOUTH CAROLINA: All the taxable property; nor may cities and towns exempt any manufactories from the duty of paying a school tax.	Consent of legislature is necessary, at least as far as districts are concerned. (Constitution.)
GEORGIA: Not stated.	Not limited; but see next column.
FLORIDA: Real and personal property.	3 mills on $1 maximum.
ALABAMA: Not stated.	
MISSISSIPPI: Taxable property and polls. (This additional tax on polls is called "additional poll tax.")	Additional poll tax not to exceed $1. (Constitution limits poll tax to $2 for common-school fund.)
LOUISIANA: Assessed value of property in each parish or municipality.	1½ to 10 mills.
TEXAS: Ad valorem tax on all real and personal property.	20 cents on $100, but this limitation does not apply to incorporated cities or towns constituting separate school districts.
ARKANSAS: Taxable property of the district.	5 mills maximum.
MISSOURI: "All subjects and objects of taxation."	(See Section A)
OHIO: Grand list of taxable property.	(See Section A); otherwise unlimited.

for the support of public schools in each State—Continued.

(VOLUNTARY)—Continued.

Conditions under which taxes not required by State (see Section A) may be laid, and for what purpose.	Conditions under which bonds may be issued, and for what purpose.
In townships, cities, and towns that are not now levying a special tax the voters shall decide as to levying such tax. Those in favor voting "for schools;" those opposed, "against schools." Certain counties are not allowed to avail themselves, or, rather, any part of those counties is not allowed to avail itself of this provision.	
Cities and incorporated towns having established higher graded schools are authorized to levy an additional tax, but not to exceed its limit of indebtedness. Also each municipal corporation of 2,000 to 4,000 inhabitants shall receive all moneys collected by it as State or county tax on property, privileges, and polls for common-school purposes, in order to enable it to sustain a high-grade public school.	
(See preceding column)..	No city or town shall create a bonded debt exceeding 8 per cent of its assessed valuation.
Any county having a "county school system" may levy a tax if two successive grand juries shall recommend it and two-thirds of the electors have voted for it. But a town having a school system of its own shall have no say in this vote. Tax for support of common schools.	
Voted by taxpayers.	
Small concentrations of population known as "city" or "town," and called for school purposes a district, are allowed by special act of the legislature to tax themselves. Thus the city of Gadsden (3,000 people) may tax itself one-fifth of 1 per cent on all property taxed by the State beyond the amount levied by the State for the lump school sum required by the law. (See Section A.)	
Any municipality, county, or separate school district (of 300 or more people) may levy a tax to maintain school after the expiration of the four months' school required by constitution in order to continue school.	
The wording of the law is "police juries (rural) and board of aldermen, etc., may levy;" but if these civil authorities fail to levy, the parish school board is directed to compel them to levy it by mandamus. Supreme Court decided that the legislature "can not force a parish to levy a [local] tax for school purposes." On petition of one-tenth of property taxpayers, vote is to be taken on question of providing buildings by increasing the rate of taxation of any parish, city, or incorporated town.	
Vote of two-thirds of taxpayers after petition of at least 20 property-tax paying voters in a district to county commissioners' court. For the purpose of continuing school and erecting school buildings.	To construct buildings and procure sites incorporated cities and towns may issue bonds, which shall not be to a greater amount than that a tax of one-fourth of 1 per cent, will pay current interest at 6 per cent, and "provide a sinking fund sufficient to pay principal at maturity."
Vote of district for school expenses. (See Section A)	By two-thirds vote districts may bond themselves up to 5 per cent of their valuation, but must also provide for interest and a sinking fund to extinguish debt in twenty years at latest.
By two-thirds vote districts not a city district of the first class may increase the tax given in Section A. For the purpose of continuing schools, establishing kindergarten, and for sites, buildings, furniture, etc. For purpose of maintaining school library of city districts the district board may levy annually one-tenth of 1 mill on the dollar.	When a majority of the electors of a district not a city district of the first class has voted taxes during a series of years for buildings and sites, the district board may anticipate the money to be thus raised by issuing bonds at 6 per cent or less. City districts of the first class may also issue bonds in the same way, save that the amount of bonds issued shall not exceed an aggregate tax of 2 mills for the next year.

for the support of public schools in each State—Continued

(VOLUNTARY)—Continued.

Conditions under which taxes not required by State (see Section A) may be laid, and for what purpose.	Conditions under which bonds may be issued, and for what purpose.
Trustees may levy tax, to be called special school revenue, for the purpose of building and all other necessary school expenses except tuition. They may also levy a tax for a supplementary tuition fund. They may also levy a special tax to pay debts.	Any incorporated city or town, by vote of the common council or board of trustees, may issue bonds for purpose of procuring grounds and buildings to the amount of $50,000, payable in one or twenty years, bonds to be sold for a sum not less than 94 cents on the dollar.
The directors of each district are "authorized," in order to support school not less than five nor more than nine months, to levy the tax given in Section A. This is taken to be mandatory upon the directors to raise a local tax.	For the purpose of building schoolhouses a district may issue bonds (by a majority vote) at 7 per cent, but may not increase its indebtedness over 5 per cent of the taxable valuation.
Voted by district for building purposes, but if a bonded indebtedness is also incurred in the same year the tax shall not exceed in districts containing less than 10 children, 15 to 20 years, $250; 10 to 30 children of same age, $500; 30 to 50 children of same age, $1,000. No legal subdivision of land more than 2½ miles away shall be taxed for such building. District meeting may also vote tax not to exceed one-half of the above for apparatus, school libraries, pay debts, and pay officers. District board levies tax to supplement amount received from State to maintain school five to nine months.	Districts may bond themselves to an amount conditioned on their school population by a two-thirds vote. But bonds must be made to mature in ten years and a sinking fund must be created by taxation. The proceeds of the debt thus incurred must be used for the purchase of sites and buildings.
Voted by district a tax for paying teachers as limited in preceding column, for purchase or lease of school, repair or furnish it, and supply it appendages and fuel, such amount as is deemed sufficient. If voters fail to vote sufficient sum to maintain school six months, district board shall levy it. High school board determines amount necessary for high school.	For building purposes and by majority vote, district may bond itself, payable in ten years, and levy a tax annually to pay interest and one-tenth of principal. (Loan shall not exceed 5 per cent assessed valuation of real property nor exceed $10,000 when loaned from State trust funds.)
Voted by legal meeting, but this is not really a voluntary tax except in amount, for it is the "duty" of the voters to levy the tax.	Two-thirds of the voters may cause bonds of district to be issued, payable in fifteen years or fewer, at 7 per cent interest or less rate, for the purpose of procuring buildings and sites. When this is done a tax must be levied to provide a sinking fund and interest. In the discretion of the board 20 per cent tax or less may be imposed to meet maturing bonds, in addition to annual levy, as related in preceding sentence.
(See Section A and preceding column).....	Bonds may be issued by majority of voters of an independent district (payable in ten years or at an earlier date) for the purpose of building or paying debt. Districts against which judgments have been rendered may issue bonds, for the redemption of which a tax shall be levied in addition to the other legal taxes.
In the case of districts by majority vote for the purpose of continuing school for more than three months. In the case of county schools for the purpose of building, paying teachers, and meeting contingent expenses. In the case of cities for the purpose of paying teachers and meeting "other running" expenses, to pay interest, and to create a sinking fund.	School district may issue bonds to the amount of 6 per cent of their taxable property if the majority of all the electors of the district assent in an election called for at the request of at least two-thirds of the qualified voters, provided there are 15 or more persons 5 to 21 years of age in the district. The proceeds of the sale of such bonds are to be used in erecting or purchasing one or more schoolhouses. In cities of the first class two-thirds vote of the board of education is sufficient to cause bonds to issue; in cities of the second class, a majority of the voters. The bonds of the cities of the first class are limited to thirty years at 6 per cent; of second-class cities to twenty years' run at 10 per cent.

NOTE B.—*Tentative statement of the sources of revenue*

SECTION B.—LOCAL TAXATION

Kind of property taxed for local purposes.	Rate or limits of voluntary taxation.
NEBRASKA: Taxable property	(See section A.) The tax for building purposes is unmistakably optional.
CALIFORNIA: Taxable property; the rate to be obtained by deducting 15 per cent for anticipated delinquencies and dividing the sum voted by the residue of taxable property.	For school purposes not to exceed 30 cents on the $100, for building purposes not to exceed 70 cents on $100.
OREGON: Assessable property, real and personal.	Not limited
NEVADA: Taxable property	do
COLORADO: Taxable property	Not limited numerically
NORTH DAKOTA: Taxable property	(See Section A)

for the support of public schools in each State—Continued.

(VOLUNTARY)—Continued.

Conditions under which taxes not required by State (see Section A) may be laid, and for what purpose.	Conditions under which bonds may be issued, and for what purpose.
Legal voters shall determine amount required for all purposes except paying bonded indebted or purchase or lease of schoolhouse. Legal voters may determine amount to be expended for school property, either by way of purchase or rent. When no bonds are voted for the purpose, but the aggregate voted for all purposes, whether current or special, shall not exceed 25 mills in any one year. In cities the board of education certifies amount to county (civil) commissioners, who levy tax.	For buildings and furnishing same two-thirds of the voters present may direct that bonds be issued as previously petitioned by at least one-third of the qualified voters. But a board of education of a metropolitan city may issue bonds by vote of a majority of the electors without a petition. Bonded debt is limited to 5 per cent of taxable property for district of 12 to 200 children of school age, but must not exceed $500 in districts of from 12 to 25 pupils, $1,000 in districts of from 25 to 50, $2,000 in districts 50 to 100, and $5,000 in districts from 100 to 200. In districts of over 200 the amount must not be more than 10 per cent of the taxable property. Interest shall not exceed 7 per cent.
By majority vote at a called election for the purpose of additional facilities for maintaining school or to build one or more schoolhouses.	On the petition of a majority of the voters an election may be called for the purpose of voting bonds for building and furnishing schoolhouses and liquidating debts. A two-thirds majority is required. The county (civil) authority shall levy a tax to meet the interest and principal as they mature annually.
Not stated	On petition of 10 legal voters of the district the board of directors may submit the question of bonding the district for the purpose of providing buildings and furnishing the same, to the electors, and if a majority so vote the bonds shall issue to an amount not to exceed 5 per cent of the assessed value of property with interest not over 8 per cent.
To provide additional school facilities and to keep schools open for a longer period than the ordinary funds will permit. The county superintendent shall certify to the civil county authority the amount required to maintain school four months, using as a basis $40 a month for teacher's salary. All other expenses of the school must be provided for by special district tax.	On petition of 20 voters of any district bonds may be issued for procuring buildings and furniture and paying debts if ratified by majority of voters. But bonds shall not exceed in amount 3¼ per cent of assessed value of property. They are to be redeemed in from five to fifteen years, and bear interest at 8 per cent or less, the interest and principal to be provided for by special tax.
(See Section A)	Majority of the district may vote to issue bonds for procuring property for school purposes and furniture. Bonds must not exceed $1,000 for each schoolhouse except in towns and villages of more than 300 inhabitants, when the amount shall not exceed 4 per cent of the assessed value of property. In addition to the amount required by law to be raised annually (Section A), there shall be levied a special tax to pay interest (7 per cent or less) and to create sinking fund.

CHAPTER XIII.

PSYCHOLOGICAL TENDENCIES—THE STUDY OF IMITATION.[1]

For previous related articles see: Report to the British Medical Association and Charity Organization Society of London, on the physical and mental condition of 50,000 children seen in 106 schools of London, by Dr. Francis Warner, F. R. C. P., London, Report for 1890–91, Vol. 2, pp. 1081–1138.—Facilities in experimental psychology in the colleges of the United States, by William O. Krohn, Ph. D., Report for 1890–91. R. Klemm, in Report for 1894–95, Vol. 1, pp. 449–460; same title in Report for 1895–96, Vol. 2, pp. 1175–1198.—Child study; extracts from address by Dr. G. Stanley Hall, Report for 1894–95, Vol. 1, pp. 1037–1040.

TOPICAL OUTLINE.—Continued progress in psychological investigation in universities, normal schools, and in circles fostered by school superintendents.—Efforts to unify the work of independent investigators.—Imitation as a leading subject.—Differences of opinion as to the primitive character of imitation, but general agreement that volition is early involved in imitative acts.—Problem for teachers to exercise the imitative-impulse within the limits of its voluntary range.—Imitation considered also as a sympathetic impulse, and hence the faculty by which social education is made possible.—Theory of M. Tarde as to the social significance of imitation prompts specific inquiries by American specialists and leads to a somewhat copious literature on the subject.—Value of the observational study of children.—Report of committee on psychological inquiry.—The psychology of the imitative functions in childhood as related to the process of learning.—Citations from a preliminary report on imitation, by Prof. J. Royce.—Extracts from the introduction to child observations, State Normal School, Worcester, by Principal E. H. Russell.

The interest in psychological study and investigation discussed in the Commissioner's previous reports shows no abatement. Universities are constantly increasing their equipment for experimental work in this field, observational study is extending among normal schools, and the circles for child study fostered by State and city superintendents are rapidly increasing. Efforts have been made from time to time to unify the independent groups of investigators, either by giving prominence to particular psychical elements, as sensations or feelings, or

[1] Prepared by Miss Anna Tolman Smith.

to particular activities, as imitation, imagination, or by question schemes that would enable scattered groups of observers to correlate their work. As the outcome of such efforts, large collections of observations have already been secured bearing upon a single psychical condition, impulse, or activity. Imitation in particular has proved a very attractive and fruitful subject. This faculty has excited attention from the time of Aristotle, but its treatment as a distinct psychological problem is of recent date, being closely connected with the scientific investigation of hypnotism. The marvelous play of suggestion and imitation in the control of motor impulses as manifested in the hypnotic subject at once brought imitation into view as a persistent and pervasive element in psychical action. Researches in the domain of animal instinct and intelligence have deepened interest in this faculty, which more than any other seems to imply the continuity of animal with human intelligence.

As regards education, the important question suggested by these investigations is the extent to which volition is involved in imitation and its relation to ultimate freedom. As to the origin of imitation in the child, whether it is purely instinctive and reflexive or partly volitional, investigators differ widely. Thus Preyer asserts: "However often imitation has the appearance of an involuntary movement, yet when it was executed the first time it must have been executed with intention—i. e., voluntarily. When a child imitates, it has already a will. But the oftener a voluntary movement is repeated, always in the same way, so much the more it approximates reflex movement. Hence many imitative acts, even in the child, occur involuntarily quite early. But the first ones are willed."

Wundt, with equal positiveness, declares: "The continued imitation by which a child comes to learn the language that is spoken round it is impulsive, not voluntary."

It is not likely that these differences will ever cease, since the interpretation of the earliest imitative movements depends upon vague memories in the adult mind or the more uncertain interpretation of infantile states. It seems, however, to be generally agreed that volition enters into imitative action at a very early period. Wundt recognizes volition in the process of learning to walk, to talk, etc. "The child," he says, "apperceives this combination of word and idea after it has been made intelligible to him with gestures, and associates it with his own imitative articulative movements. Following the pattern of these first apperceptions and associations, the child then forms others by imitating of his own accord more and more the words and verbal combinations that he accidentally hears adults using, and by making the appropriate associations with their meanings."[1]

Compayré, who denies volition in the earliest imitative acts, says: "Imitative movements, as soon as they become conscious movements,

[1] Outlines of Psychology (translation by Charles Hubbard Judd), pp. 292, 293.

pass under the control of the will. Then instinct disappears and individuality begins."[1]

Baldwin, who, like Compayré, recognizes a gradual development from impulsive to voluntary imitation, agrees also with him in regarding conscious imitation as involving volition. At the moment the instinct to imitate becomes a matter of consciousness, then, to quote Professor Baldwin's own words, "the mental copy, seen, heard, remembered, is set up and aimed at; imitation is no longer the organism's weapon; it is now the sword of the mind."[2]

And again: "In saying that volition—the clearly conscious phenomenon of will—arises historically on the basis of persistent imitation, what I mean, is this, that the normal child's first exhibition of volition is found in its repeated efforts to imitate something."[3]

Bain regards all imitation as voluntary in its nature. His utterance on this point is emphatic. "The voluntary command of the organs," he says, "means the power of imitation or of performing actions in consequence of seeing them performed."[4]

Froebel, who dwells ever on the self-activity of the child without analyzing its elements, recognizes that imitation and spontaneous activity are both manifested in the early plays of boyhood.[5]

The school of physiological psychology, of which Ziehen may be taken as the representative, finds no ground for the "assumption of a special faculty of the will," but emphasis is placed upon the relation between practice and the desired accommodations of the cortical mechanism, characterized by Ziehen as "an apparatus highly adaptable to the training of voluntary actions."[6]

Whatever meaning be attached to volition, attention to a model and conscious effort to reproduce it involve voluntary effort; hence, and this is the point of great significance to teachers, up to a certain point imitation may be regarded as not only a means of quickening perception, but also of strengthening the will. It is to be observed, further, that through the ever-increasing comprehension of relations, causes, and principles in the thing imitated there is gradual assent to free activity. This process is illustrated in the development of many of the chief artists of the world.

The notion that imitation represses originality is not well grounded, on the contrary, it will generally be found, as Bain has pointed out, that "in whatever department any individual shows spontaneous and unprompted facility, in that department will the same individual be

imitative or acquisitive?"[1] It must, however, be recognized that repetition tends ultimately to make action mechanical, so that the limit of progress in a specific direction through mere imitation is soon reached.

One of the important problems ever before a teacher is that of the exercise of the imitative impulse within the limits of its voluntary range.

Nor should imitation be considered solely from the individual standpoint. It is essentially a sympathetic impulse. Says M. Compayré, "Sympathy must be included among the auxiliaries of imitation; sympathy taken in its double meaning, either as the faculty by which we participate in the pains and pleasures of others or as the inclination which attracts two persons toward each other and inspires them with a mutual affection. In the former sense sympathy is in truth only imitation itself, a moral imitation, since it is merely the secret need of bringing our sentiments and our thoughts into accord with the thoughts and sentiment of others." It follows that imitation is the means of social development, it is the faculty by which social education is made possible. This aspect of imitation was elaborated in a striking manner in a work by M. Tarde on The Laws of Imitation. In this work the author seeks to separate as completely as possible the purely social side of human actions from the vital or physical elements in them. He purposes to sketch a pure sociology, or rather general sociology. The laws of this sociology, as he conceives them, should be "equally applicable to all actual societies passed or possible as are the laws of general physiology to all animals living, extinct, or conceivable."

In the endeavor to find reasons which adequately explain the entire series of social events and which exclude any other possible sequence than that in which events actually occur, M. Tarde explores the whole field of human activity, language, religion, society, industry—he establishes analogies between movements here and those in the physical domain and determines that social phenomena, like physical, repeat themselves with constant regularity.

From the analysis he reaches the proposition that the social order develops from individual initiative through imitation. "In the social order" he says "there is nothing but invention and imitation" (Tout n'est socialement qu'inventions et imitations). Whatever exaggeration may be detected in this exclusive proposition, the work of M. Tarde is of interest here because it seems to have prompted the investigation proposed by Professor Royce in 1894, and popularized by an article in the Century Magazine (May, 1894). In this article, which discussed the whole subject in a light and discursive manner, Professor Royce submitted a schedule of questions intended to secure responses from the most varied sources.

[1] The Senses and the Intellect, fourth edition, p. 440.

The questions were not designed merely to accumulate examples of imitation. They included what are termed "original imitations;" that is, instances where the chosen model or elements serve as a medium for the expression of the inner self. Such are the dramatic impersonations or "systematic mimicry" in which many children indulge. Imitative naughtiness was also specified as a field for investigation and early manifestations of "sympathetic emotions," which enter so largely into the moods of the masses.

Also as a means of completing the study of imitation, Professor Royce asked for accounts of the reverse function, the willful tendency that causes certain children to react against all models. These inquiries indicate that imitation has a deeper significance for Professor Royce than mere repetition, upon which M. Tarde places chief stress. Professor Baldwin, in an earlier article,[1] had considered the genetic development of imitation from the organic to the voluntary stage. Incidentally he showed, also, defects in M. Tarde's theory, especially its failure to recognize choice and judgment as to a model consciously followed.

Although others were working at the same problem, it was in particular the articles by Professor Royce and Professor Baldwin that made imitation the chief subject of interest in school circles, and the result has been a copious and varied literature of more or less interest to teachers. The committee on psychological inquiry of the national council took up the subject of imitation as related to the process of learning. Their report will be found in full in this chapter.

Professor Baldwin's Mental Development in the Child and the Race, published in 1895, elaborated the author's own conception of imitation, tracing its relation to the whole process of mental growth. Amid much that is conjectural, admittedly so, in the theory advanced, the work abounds in suggestions stimulating to the teacher. A preliminary report on imitation was made by Professor Royce before the meeting of the American Psychological Association December, 1894, and published subsequently in the Psychological Review (May, 1895). The report was especially characterized by the effort to classify and define the several processes which are commonly recognized by psychologists as imitative, and it was extremely happy in its exposition of the subjective phase of the process. A portion of the article bearing on this view is cited below.

Among the records of observations or accumulated examples of imitative arts, two should be noticed particularly; the first, entitled, "The suggestibility of children," by Maurice H. Small, fellow of Clark University; published in the Pedagogical Seminary of December, 1896. The study related to the effects of suggestion rather than to imitation, but as imitation is the most constant outcome of suggestion, the record naturally turned upon this activity.

[1] Mind, January, 1894.

It is of special interest to note that this record was made possible through the cooperation of superintendents and teachers in many States, who responded to the syllabus sent out from Clark University. The collection is intended to illustrate the influence of suggestion upon motor impulses, but as might have been expected from the conditions under which the data were collected, the relation between the main trend of the discussion and the particular instances is often vague or forced. Mr. Small hints at a method of instruction and discipline by suggestion without explicit characterization. The experienced reader will recognize that it is an influence ever present in school life, but not easily defined or regulated.

The volume of child observations, first series, Imitation and Allied Activities, edited by Miss Ellen M. Haskell, of the State Normal School at Worcester, comprises observations made by the students of that institution. The principal, Mr. E. A. Russell, furnishes an introduction which sets forth very distinctly the purpose, the limitations, and the advantages of this particular kind of child study. Copious extracts are cited in this chapter from Mr. Russell's introduction to meet inquiries upon these several points which are widely discussed in normal schools at the present time.

This survey, though confined to a single line of inquiry, may serve to indicate the trend and method of observational psychology as fostered at many centers in this country, and the efforts to correlate these observations with the more exact investigations of specialists. The actual value of such observations in extending our knowledge of psychical life appears as yet somewhat problematical, but there is abundant testimony to its admirable effects in kindling sympathy for childhood, and thus increasing the personal influence of teachers in guiding and developing their pupils.

The opinion expressed by Professor Burnham, of Clark University, is constantly reiterated by other leaders of child study. "It is," he says, "primarily for the teacher, secondarily for the children, incidentally for science."

REPORT OF COMMITTEE ON PSYCHOLOGICAL INQUIRY — THE PSYCHOLOGY OF THE IMITATIVE FUNCTIONS IN CHILDHOOD AS RELATED TO THE PROCESS OF LEARNING.[1]

By Wm. T. Harris, Chairman.

The undersigned committee on psychological inquiry beg leave herewith to present their report, calling attention to a new and promising opening for educational psychology, which has been made

[1] Reprint from Proceedings of the National Educational Association of paper read before the National Council at Asbury Park, N. J., July 7, 1894.

through a study of the imitative functions in childhood with a view to explain mental development and the process of learning.

The felicity of this selection of imitation as the opening study in the psychology of education will appear upon consideration. For imitation, in its purest and simplest form, that of mechanical repetition of the actions of another person is, by common consent, placed at the bottom of spiritual achievements. A monkey or a parrot can mimic actions or speech, and to call the action of a human being parrot-like repetition or a process of aping is to express reproach and contempt for it. What teacher is there that does not despise mere verbal repetition in his pupils? Can there be a greater paradox in educational psychology than the theory which sets out with the function of imitation, and attempts to show that all forms of intellectual and moral activity are only varieties of this despised mode of action? If there is an attractive method of bringing psychology to the attention of teachers surely it has now been found. The sheer audacity of the theory that places the stone which the teachers had rejected for the head of the corner will fix the attention alike of the primary school mistress and the professor in college.

But there is a consideration connected with imitative action which makes it the most fruitful approach to psychology, for it explains the mode in which the individual man unites with his fellow-men to form a social whole. It introduces us to the formation of institutions, the family, civil community, the State, the church—those greater selves which reinforce the little selves of isolated individuals. For the study of imitation leads to the discovery of the modes by which the individual man repeats for himself the thinking and doing and feeling of his fellows, and thus enriches his own life by adding to it the lives of others. Thus his own life becomes vicarious for others, and he participates vicariously in the life of society.

What are manners and customs but imitated forms of doing, that preserve the results of successful experience in dealing with nature or in cooperating with one's fellows? What is fashion, with its apparently capricious changes, but the method of emancipating individuals from the tyranny of old customs and usages, that insist on minute punctilios in matters that are unimportant, except as symbols of our membership in the social whole? Thus one kind of imitation supplants another as more progressive. The fashions of the semicivilized and savage people last without change from generation to generation—and, indeed, it is likely for hundreds, and even for thousands, of years—because the savage intellect can not as yet attain the strength to discriminate between moral and indifferent actions. The savage has only two kinds of deeds—moral and immoral; while the civilized man has three kinds—moral, immoral, and unmoral. Thus that form of imitation which we all despise as mere fashion has sig-

nificance as the means of emancipating us from that heavy yoke of ceremonial that once prescribed the forms of our indifferent actions as though they were of moral or religious import.

Imitation develops, on the one hand, into habits, or customs and morals, and this is the will-side of human mind; and, on the other hand, it develops into perception, memory, ideas, and insights, this being the intellectual side of mind. It is evident that the pedagogic interest in psychology is the evolution of the higher faculties out of the lower. It is all-important for us to understand this progressive step by which free moral action develops in the place of mere unconscious use and wont. We must discover how mere external memory of borrowed ideas gives place to insight. It is necessary, first of all, to discover the most elementary forms of imitation. In this research the students of physical phenomena have greatly aided. The discovery of the fact that a small per cent of people are so sensitive to the mental influences about them that they can, without the intermediation of words, read the thoughts of others has been made and verified in numerous instances. The study of hypnotism has taken up this fact into a class of related facts belonging not only to the intellect but to the will and the emotions as well. The phrase "hypnotic suggestion" has come to play a great rôle in elucidating the rudimentary facts of imitation. The hypnotizer suggests an idea, which the hypnotic subject takes up and carries out in feeling or action. The rapid progress of scientific investigation in this field of psychic research promises to throw light on all social thought, feeling, and action. It will help us to understand much that has been obscure in the rise and spread of popular beliefs, the genesis of social tornadoes, like the Crusades, the French Revolution, the Tartaric invasions of Europe, or even such local affairs as strikes and mobs.

We must not lose sight of the essential fact that shows itself even in the most rudimentary of the phenomena of imitation. There can be no imitation whatever except on the part of self-active beings; in other words, only souls can imitate. "Imitation," says Compayré, "is the reproduction of what one has seen another do." It is therefore always to some extent an act of assimilation. Even if we extend the meaning of imitation so as to include unconscious mimicry and all phenomena akin to hypnotic suggestion, still it is self-activity that does the imitating. What is beheld as an act of another is converted by adoption into an act of self. The pride and pleasure that the infant exhibits on the occasion of his first conscious imitation has its root in this, that he has made something his own, has proved himself equal to imitating a movement in himself by his will; he has revealed his selfhood to some extent. This is the significance of play, which is chiefly imitation, that the undeveloped human being is learning to know himself by seeing what he can do. He is reveal-

ing himself to others and to himself, and getting strength in his individuality.

Thus we see that there is an element of originality in the most mechanical phase of imitation. The self is active and assimilative. It sees an external deed, which it proceeds to make its own deed by imitation.

It proves itself to possess a human nature identical with the one whom it imitates.

Originality grows by progressive deepening of the insight into causes and motives of the thing imitated. The lowest stage of imitation superstitiously imitates all the details, because it has no insight into the grounds and purposes of the action imitated and but little comprehension of the means employed. When it understands the means and the motives, it strikes out for itself and makes new adaptations. It modifies its imitation to suit differences of circumstances.

Originality grows with this ascending comprehension of means and purposes. There comes a time when the imitative child comprehends the principle as well as does the master whom he imitates, and then he is emancipated from all imitation in this part of his education. If he keeps on and comprehends the genesis of the principle from deeper principles, he emancipates himself from even the "hypnotic suggestion" of the principle itself, and all external authority has become inward freedom.

M. Tarde, who published his great book on the Laws of Imitation in 1890, speaks of self-imitation, as in the case of habit (p. 83), which he defines as a sort of "unconscious imitation of one's self by one's self." Here, in the stages of originality, where the person has learned to comprehend what he once imitated, and now understands it in its causes and in the reasons for its existence, is self-imitation, if we are to speak of imitation at all. It is no longer an activity at an outward suggestion, but purely spontaneous. It has vanquished the external object by ascending to its causes.

It is worthy of note that this book of M. Tarde is a study of sociology; for, in the French Revolution, the thought of Rousseau produced individualism, and the social whole was denied a valid existence in the shape of the State, except in so far as it appeared as a free contract between individuals. It was not considered that any contract presupposes a preexistence of state or government, a social whole to give validity to the contract. It is well that this new movement in psychology, which proves the substantial basis of mental evolution to lie in social institutions, should receive its great impulse from a Frenchman. M. Tarde is the anti-Rousseau.

The profoundest thinker of the human race, Aristotle, hits upon this subject of imitation in his Poetics, making it the basis of his philosophy of art. What he says in the fourth and ninth chapters of

the book on the subject of Mimesis, or imitation, rather leads us to see a deeper meaning in the word than mimicry or mechanical repetition. It seems almost to mean symbol making. "Man is the most imitative of animals, and makes his first steps in learning by aid of imitation," he tells us. Man is a symbol-making animal always, in whatever he does; making a symbol of what he is in his essential nature; always repeating in himself the symbols of the existence and actions of all other beings.

Leibnitz, the philosopher who translated Aristotle's ideas for modern readers, has told us in his monadology that each soul is a monad which, by its self-activity, repeats for itself or represents the whole universe. This is imitation on a grand scale—imitation transfigured, we might say—that, by self-activity, assimilates the whole universe. The monad creates for itself the world that it perceives. Here, we see, is the harmony of freedom and authority. The soul is not determined by what lies outside it, but determines itself so as to reproduce the beings and the causes that are outside it.

Here, too, is the social man again of M. Tarde; for each man has this one destiny, to sum up in himself the life and deeds of the race.

The latest great world poet, Goethe, in his Wilhelm Meister, treats the problem of culture or education, in its widest sense, in connection and contrast with the problem of dramatic art—how to make an actor. The individual sees ideals above him, and impersonates them; loves them, and imitates them; wears them as a player acts his part. Gradually he acquires as a second nature his ideals, and must keep growing on into new and higher ideals. The mere actor (he shows) must be able to assume quickly all characters, and yet possess no character himself; he must be a sort of professional wig block to hold, one after another, all kinds of wigs, but to have not even a scalp of its own. Goethe's favorite characters were those who react against their environments by internal development. They always press beyond imitation toward the indwelling principle of that which is imitated, and thus attain freedom. Prof. Mark Baldwin, now of Princeton University, was one of the first to take up and develop this function of imitation as the key to educational psychology. His articles in Science, in 1891 and 1892, and more recent articles in Mind, 1894, and, finally, his work on Mental Evolution in the Child and the Race, form a large and valuable contribution to this study.

Prof. Josiah Royce, of Harvard, has taken up the same theme, and with the extensive resources at his command has presented it in more suggestive and more popular forms than had been done before. Those who have read his charming article in the May number of the Century on "The imitative functions and their place in human nature" need not be told so much as this.

Your committee in this their report have not attempted to illustrate the application of this important category of imitation to the

subject of the process of learning in childhood, but have preferred to leave this illustration for the round table discussion of Monday evening, in which Professor Royce has consented to assist and give his own presentations of one of the phases of this theme.

Respectfully submitted by

W. T. HARRIS, *Chairman*,

N. A. CALKINS,
Committee on Psychological Inquiry.

EXTRACTS FROM A PRELIMINARY REPORT ON IMITATION, BY PROF. J. ROYCE.[1]

Imitation of motor functions.—"To us all the word imitation first suggests motor functions, such as those of the child that struts about as a soldier, or that runs on all fours as a dog, or that learns to talk. Such functions are very numerous. We observe them in many animals, including birds. Their characteristic is that the imitator is more or less clearly aware of a model, and finds his own body more or less able to repeat certain usually extensive and complex movements of this model. This repetition gives satisfaction to the imitator. Imitation of this sort is to be roughly classified as either more or less critical. Sometimes the imitator is content with the roughest reproduction. Sometimes he is cautious, and is watchfully anxious to do precisely as his model does. A mocking bird, as I at one period often observed in the case of a household pet, appears to study, with very great care, at least some of the series of notes that he reproduces. Some children far surpass others in an early pedantry about the enunciation and use of their words. In any case, meanwhile, the subjective experiences of the imitator are here, at best, only in part identical with those given him in the stimulus presented to his senses by his model. He hears sounds and replies by sounds, but of course he feels more or less the muscular and other organic disturbances incident to the reproduction. He sees the movements of his model. He both sees and feels his own imitative movements, and in all this he feels the latter as his own. In consequence, the imitator usually takes what is often called a decidedly subjective sort of interest in his power to imitate. His activity has thus two strongly contrasted aspects. He watches his model, so far as he watches it at all, with a highly objective faithfulness. So far, his imitation depends upon a theoretical and very self-surrendering sort of outward scrutiny.

"On the other hand, he delights in his own imitative powers as his

[1] Psychological Review, May, 1895.

own, i. e., as corporeally interesting events in his own organism, just as even the mocking bird very obviously does. On this side the activity is, in the popular sense of the word, as self-centered as is eating or catching prey. That is, it is an activity whose conscious aspect involves an interest in interorganic experiences. And, on this side too, the imitative process in our children is a great meeting place about which all sorts of self-considerate and self-conscious interests gather. Thus one sees how highly interorganic, or subjective, as well as how highly outward-looking objective, the imitative consciousness in the present class of cases has to be. Hence the enormous fecundity and various outcome of such imitative interest. Vanity and conscience, ideal devotion and flippant mockery, tame subserviency and the loftiest originality—all these tendencies alike may, and in fact normally do, take root in this fruitful soil, and any of them may grow into the child's later character, and all because he was, in the first place, disposed to repeat the complex motor processes of his models, and so was forced to set off his consciousness of his own movements against his perception of the movements of others, thus emphasizing both his ideas of himself and his ideas of his models, each set of ideas by contrast with the other set. Imitation may thus become, to use the words again in their purely popular sense, the most self-abnegating or the most self-considerate of tendencies, according as, in the end, one or the other of these opposing drifts of attention gets emphasized, i. e., according as one comes to consider rather his own imitative organism or the outside model."

Imitation of intelligent functions.—"So much for a first and most familiar class of processes defined as imitative. But we, all of us, extend the word imitation to include those intelligent functions which tend to the voluntary production of external objects resembling certain other objects called the models of the objects produced. Thus drawing, painting, modeling, building, mechanical skill of all sorts, are universally named imitative functions. In our own cases such functions, as a class, are obviously almost altogether derived, directly or indirectly, from the functions of the former class just characterized. We learn, namely, to reproduce things, in whole or in part, by first having learned to imitate people. Mechanical skill may early become self-directing. But it is probably always, at the start, socially guided. Psychological complications are, accordingly, here of much the sort as in the foregoing class of cases. Our imitations of objects involve vast numbers of relatively controllable conscious processes besides our perception of the finished products which resemble the stimulating models. And here, too, in consequence, both our relatively objective or outward-looking, and our relatively subjective or inward-looking interests get a correlative development as we learn to imitate a development which may have the utmost complexity and the most momentous psychological consequences. On the whole,

however, the imitation of things generally tends, as they say, to send us out of ourselves, i. e., outside of our interest in the processes of our own organisms, still more than does the imitation of the mere acts of people. Our imitative deed is transient; but, when we make something by the deed, its product here remains to calm our more anxious or our vainer interest in our own motor processes as such. Hence it is that musicians are more subjective in mood than are architects; and it is easier to be vain about matters of social etiquette than about one's skill as a carpenter, in case one has any such skill; while, to pass to another case where imitation is complicated with originality, nobody can judge his own book while it is in press as he can after it is in cold print and binding before him."

General nature of imitation.—"Now I have laid stress upon the factors present in these two classes of cases of imitation, because I have meant to use them to illustrate the general nature of imitation itself. In these two classes of cases imitation is not merely, as a psychological process, the reproduction of a series of sense stimulations, or of external perceptions by means of a series of motor processes; but it is something still more complex. It is not only a process by which we reproduce one set of data by means of another set of data like the first, but it is also a process by which we get two sets of data whose inevitable contrasts are as interesting and as instructive to us as their purposed resemblances. We get an interpretation of the perceived model through the imitation of it. On the other hand, to say that imitation in these cases is an act whose main motive is to interpret my perceptions by means of my deeds, is indeed true; but, of course, so far the same might be said of all those acts, such as looking, listening, approaching an object, grasping, touching, handling, exploring in the perceptive field—of all acts, in short, which involve intellectually valuable motor processes. What, then, is the characteristic feature of the imitative acts in the mentioned classes of cases? Does it not obviously lie in the fact that my interpretation of what I am usually said to perceive outside of my organism in the external world, is in the case of these classes of imitations, conditioned upon my setting over against my perceptions a series of motor processes, or of perceived results of motor processes, which in its wholeness contrasts with the other series in the one principal fact that the motor processes, the imitative deeds or their results, appear to me relatively controllable, plastic, reproducible at will, while otherwise the two series are largely similar.

"When I learn to grasp an apple, the grasping is, indeed, once learned, an easily reproducible and so controllable deed, and on suggestion is remembered as such. But when I learn to say *apple*, upon hearing the word pronounced, the act, once in my power, is felt as controllable, but as to result it resembles its model (namely, the word apple, pronounced by my neighbor)—something that concerns not its

controllableness, but some of its other characters. Thus in these cases imitation is definable, from the psychological side, as an act that interprets an uncontrollable perceptive series by setting over against it a series of experiences that appear to be similar to it in content, but to be also in contrast with it by virtue of their controllableness. Or, again, an imitation is an act that tends to the interpretation of what is beyond my power, or is independent of my movements, by contrasting it with what otherwise resembles it, but is in my power and is a result of my movements. This feature of imitation, viz, that it accomplishes the aim of throwing light on the uncontrollable percept by setting the controllable deed beside it, is, I suppose, the principal intellectual function of the higher imitative life."

Idealization of imitations.—"This principle of the tendency to deliberate idealization of our imitations, to deliberate deviations from the literal, one finds, then, in the most varied forms, in play, in art, in the far-reaching and deep-seated tendency, very complex in its origin, to translate space relations into time relations, and vice versa, in every form of fondness for what one may call symbolical motor processes; and so, finally, with very momentous consequences, in all those motor processes that are connected with the growth of our theoretical thinking. That our thoughts are in this general sense conscious processes by which we constantly mean to imitate the tenet of the things that we experience, is perfectly obvious. Equally obvious is the fact that to think experience is to translate it into terms which are decidedly foreign to its character as it comes to us, apart from such ideal reconstruction, and in its first intention. Now, thinking accompanies motor processes, abbreviated and truncated and rendered abstract in all sorts of ways, but very obviously and highly imitative in all the cases where we get them in any relatively unabridged form.

"The gesture language is a case in point. It gives the gesturer trains of experience of a very complex character, which are in a summary and more or less symbolic fashion similar to the primary trains of experience which by his gestures he undertakes to describe. For gestures we who speak have now learned to substitute trains of words, which we follow with an endless chain of attentive processes shifting from one series of images to another. But the series of attentive processes, as it follows now these, now those images, gives us a total inner experience which we call an account of the experienced reality beyond the thinking process. The value of this account we judge by its resemblance, not in detail, but in its total network of related elements to those aspects of the relatively external experience which our thinking means to emphasize. And yet, on the other hand, how unlike their originals our abstract ideas mean to be. How far is the thinker's imitation from being a mere inner reproduction of the external experience about which he thinks? It is the very contrast which here enlightens us, when it is accompanied by a consciousness of the

sort of agreement which we all the time intend. In symbolic imitation the imitative subject means to neglect all of his model except his own chosen aspect of it; and even this aspect he generally means to reproduce in terms of a sort of inner experience which differs from it as widely as the data of one sense * * * can differ from those of another."

Imitation psychologically defined.—"Imitation and model are contrasted series of presentations whose relation keeps them apart. And hence it is that, as I myself suppose, imitation is, psychologically speaking, the one source of our whole series of conscious distinctions between subject and object, thought and truth, deed and ideal, impulse and conscience, inner world and external world—in short, of all those familiar and fundamental rational distinctions which psychology has hitherto found so baffling. The contrast between model and imitation is, to my mind, the first appearance in consciousness of that differentiation which in the end makes internal and external experience not merely qualitatively different—as, of course, they more or less are from the first—but consciously discriminated, as at first they seem not to be."

EXTRACTS FROM INTRODUCTION TO CHILD OBSERVATIONS, STATE NORMAL SCHOOL, WORCESTER, MASS.

Mr. E. H. RUSSELL, Principal.

Aim of the observations.—"The main object in making and recording the observations that constitute the present volume has been to put our students who are preparing to be teachers en rapport with children."

* * * * * * *

"The aim has been not a scientific study of children in the interest of psychology, but an attempt to bring our future teachers into closer and more sympathetic relations with them as individuals. In this respect the undertaking has proved highly successful, and it pretends to nothing more."

* * * * * * *

"Wholly new discoveries in the domain of child nature are scarcely to be looked for; but rather a more careful exploration, fresh points of view, better insight, juster emphasis, something like a new reading of an old and familiar book. Our own observers have been especially encouraged to seek for the naive and spontaneous activities of children, rather than for what is exceptional or responsive to suggestions from parents and teachers. The conditions most favorable for this kind of observation are perfect freedom and unconstraint on the part of the child, and, if possible, complete unconsciousness of being the object of special interest or attention. This, of course,

requires much tact and self-effacement in the observer; but I think the following pages will show that such tact has not been wanting."

* * * * * * *

"It has seemed to me of prime importance to keep the motives and direction of this study of children right end foremost; that is, not to forget that we want to know children in order to enter into fuller sympathy with them, not to let the knowing, however scientific, stand as the sole end in view—save in the case of a very small number of devotees of science for its own sake, and even here I should be very particular about requiring such to show their credentials. I deem it better not to urge young teachers to assume the scientific role, to think that nothing short of this or other than this is of any dignity or avail."

* * * * * * *

"It has been objected that the value of these contributions is vitiated by their fragmentary and detached character; and it has been suggested how vastly more conclusive and satisfactory they would be if accompanied by such particulars of time, place, and circumstance as would give them an ampler background and perspective. Perhaps so. But we encounter two main difficulties here. First, the ancestry, environment, and personal history of any child, in such degree of minuteness and accuracy as could be of real service, are matters by no means easy to come at. And again, if such details were put before us, it would be found exceedingly difficult to trace their influence upon the case in hand. The river of childhood does indeed run by our very doors, but the springs that feed it are mostly beyond our horizon. We can not begin at its sources, because we do not yet know them. They are precisely what we are trying to discover; and our only way is to note in which direction the current flows, and then follow it upward as best we can. In such a study as this a vast body of facts must be accumulated before their connections and dependencies can be made apparent; and these facts will often be like the arrow points and potsherds which the archæologist treasures up, until at length by their variety and numbers they flash into relations and unities which singly they could give no hint of. All work in inductive science must be superficial before it can be deep. We can never take the second step first. But further than this, it is not clear that, in the great majority of cases, a given childish act would receive much, if any, illumination from such particulars of the child's surroundings as would be accessible to an ordinary observer; for example, the age, nationality, and occupation of parents and grandparents, number and ages of brothers and sisters, outline sketches of nurses, playmates, and other companions, social and pecuniary status of the family, location of the home, personal history of the child from birth, etc. In children presenting marked abnormal peculiarities (not more than 1 or 2 per cent of the whole), such

facts might indeed have important significance to a medical man; but that would mean a wholly different kind of investigation, and one obviously not within the purview of the present study. The influence of heredity and environment, especially the former, is by no means as yet so fully made out and understood, even by specialists, that its application as a factor in every case can be readily perceived, and made serviceable. If any reader will take the trouble to look at a dozen of the records that follow, taken at random, and then ask himself the question just how and in what respects they would be rendered clearer and more conclusive by any use he could make of such personal details as have been enumerated, I should be glad to hear his answer. No one doubts, in general, that such facts do have some bearing on each particular case; but it is quite another matter to say definitely what that bearing is, and how it is to be traced and its connections shown.

"I suspect that the state of our knowledge is not sufficiently advanced for this, and will not be for a long time to come. Nor has the thing been attempted, except in a very loose and sketchy way, even by those who have given us the most minute and systematic accounts of individual children—as Preyer, Darwin, Tiedemann, Miss Shinn, or any other, so far as I am aware; least of all, perhaps, by Professor Sully, in his Extracts from a Father's Diary, who yet deplores its absence from the Worcester records—of which, nevertheless, he does not fail to make good use in his latest volume. It seems, therefore, a superficial, if not captious, demand to ask that these records of ours should be loaded with a marginal accompaniment of facts (even if they could be had) that nobody has hitherto found it feasible or thought it worth while to give, and which, if furnished, could not be to any useful extent interpreted or applied. To hold a child, 'root and all,' in your hand, to transplant to your notebook even its smallest act with all the rootlets and soil, racial and individual, adhering intact, is a feat of far greater difficulty and delicacy than is implied by the easy remark that we 'ought to have more' of the circumstances, associations, etc., in order to form a satisfactory judgment. I think we need to know much more of what there is in children before we are ready to attack the questions, how much there is, and how it came there."

* * * * * * *

Reflections upon the observations.—"The thing that has struck me most forcibly in my delighted perusal of these records is the spirited way in which the imitative acts of children are carried on—the unflagging repetitions of the same simple things, and the ready support and transfiguration that fancy lends to barren details and materials, creating from moment to moment fresh interest and variety. It has seemed as if I were privileged to stand at the fountain head of life and see its waters bubble forth from exhaustless hidden depths as by perpetual miracle.

"Next to this buoyancy of spirit, as a source of interest, comes, perhaps, the suprising accuracy of children's earliest imitations. How unerringly the little actors seize upon the very 'pith and marrow' of much that goes on in the new world around them, and with what a sure and even artistic touch they often reproduce it and give it the right emphasis in their play. The abounding fancy which they display is not fancy merely, but is at the same time well anchored to truth, and shows a grasp of the act imitated, in its essence and meaning, that is remarkable in being so much beyond the child's power of description and speech at that age. There is thus a language of things and events that speaks to the child, and is understood by him, and intelligently responded to by his imitative acts, long before he is able to comprehend and use conventional speech. Here is an avenue and vehicle of acquisition and expression that antedate even the mother tongue. And this fact, by the way, suggests the question whether our school-teaching does not too soon turn away from this natural and universal language, in which the child shows himself such an adept, and unwisely attempt to replace it with arbitrary and artificial word signs, a later and more complex acquirement, both in the race and the individual, and one for which the infant's powers are not yet ripe? Whether there is not at this age a considerable tract of time wherein, by a simple method of example and imitation, and mostly in silence, a child might be taught many things more effectively, with less strain and confusion of mind, than under conditions which involve the usual accompaniment of pedagogical verbiage? In a word, since children are on the alert for things to do months and years before they have any ear for wordy explanations, could not their first teachers borrow with advantage something from the art of those who instruct the deaf?

"Again, the expansive and progressive character of play from year to year is noticeable and suggestive. It begins impulsively with salient and detached acts—

'Some fragment from his dream of human life'—

and only by slow accretions comes to embrace accessories and relations. Thus the observer is often able to seize and record, in the simplest imitative effort, practically its whole scope and meaning. There is no motive but impulse, and there are no traceable connections; the curtain falls and the scene is at an end. Then—

'The little actor cons another part,'

which in its turn may be similarly recorded. So it happens that these records, by what at first seems their too fragmentary and disconnected form, really afford a true representation of a pronounced trait of early childhood, namely, the jerky, staccato movement of its activities. The development of a child's intelligence, like the ossification

of its bones, appears to begin at isolated points and to spread gradually until contact and continuity are slowly established."

* * * * * * *

"The child is an apprentice. The art and mystery of life lie before him, no longer primitive and simple as in prehistoric ages, but developed and expanded into the thousand forms, usages, and institutions of modern civilization. These it is his task to learn and practice. And it is to this long and arduous undertaking that the infant, happily unmindful of its magnitude, applies himself betimes and with joyful and indomitable alacrity. He attacks the problem, as we have said, first, by resolute and manifold activity, beginning with the reflex and instinctive, which gradually merge into the purposive; secondly, by imitation and mimicry, also impulsive and fitful at first, and finally, as reenforcements of intelligence arrive, by more expanded and systematic games and sports, which eventually carry him to the threshold of maturity. This, in rough outline, is the sketch and plan of his procedure, which, indeed, is but a conforming to the necessities of his situation. The serious work of life is far beyond the powers and ken of a child. In physical ability and in understanding he must long remain a weakling and dependent. But he inherits a patrimony of instincts, and though he seems at first to squander this in many prodigal and aimless undertakings, he is thereby continually gaining valuable experience. He casts about for an opening into the attractive activities that he sees going on in the adult world around him, and, reckoning perforce with his immaturity and impuissance, straightway adopts, as the only profession possible to his small executive powers, the drama. The long-past achievements of his ancestors reverberate and tingle in his blood, impelling him to action; but all his efforts are ludicrously futile beside those of the giants about him and meet only with indifference or jeers. The world of law and order and systematic endeavor is too tough for his assimilation. It must first be softened into myth and make-believe by the solvent juices of fancy, which the glands of his little mind fortunately pour out in abundance. He can not live life; he must dramatize and play it. So he becomes an actor, an amateur in the good sense—

> 'Filling from time to time his "humorous stage"
> With all the "persons," down to palsied age,
> That Life brings with her in her equipage.'

Thus in imitative play, in obedience to the biologic law of recapitulation, the child epitomizes and rehearses the fundamental experiences of the race at the same time that he is sounding the depths and shoals of his own nascent powers, and thereby preparing day by day to take part in the real work of life which the coming years will bring. Play is thus seen to be at once reminiscent and anticipatory, a welding of the future to the past. This is the child's season of

apprenticeship, his Wanderjahre; it comes but once; nor is it easy to see how it could be essentially narrowed or abridged without entailing serious loss of that vital continuity and momentum which is the mainspring of human character and achievement. The welfare, not only of the individual, but of the race, demands the widest sweep and fullest play of this deeply rooted instinct, and any ideal or regimen of education that proposes or tends in the least degree to cut it short by meddlesome repression or substitution is little less than a crime against the race.

"A striking thing about the imitative play of children, as revealed on almost every page of the following records, is the way in which it is made to minister to what may be called the instinct or passion of self-exaltation, the restless and impatient craving of childhood to get beyond and above itself, to leap into the future, and assume the dress and ways of grown people. The actual status of the child, as I have said, is weakness and insignificance itself, and his real advancement is snail slow. But by laying hold, through imitation, of the adult activities around him, he seems to pull himself up where he yearns to be, becomes of consequence, at least in his own eyes, is 'transported beyond this ignorant present, and feels now the future in the instant.' The leverage thus gained is of signal advantage to the child, both as a source of present enjoyment and as supplying the needed spring and impetus to further improvement. Where this propensity is lacking, as usually in the case of the idiotic, there is no motive, and all progress is at a standstill. And it may be remarked, in passing, that school life, so far as it operates to check and restrict this spirit of imitation and play, annuls the most powerful of childish motives, and tends to reduce the pupil for a time to a stagnant and semiidiotic condition. The sway of the self-exalting disposition, though in general so salutary, does sometimes play into the hands of precocious development, and may, if taken seriously and seconded by parents and teachers, become one of the gravest of dangers, for it marks a tendency to revert to a lower and shorter cycle of growth. The sun should not go down upon any pronounced symptom of precocity in your child; let this be checked betimes, not by rebuke, but by the starving process of turning your back upon it."

* * * * * * *

"We say, from the adult point of view, that little children are quick to see resemblances, and we ascribe this to their acuteness, but it is really the opposite; it is rather the obtuseness of undeveloped perception which fails to take note of the large escort of dissimilarities that, to experienced eyes, always accompanies and often obscures the features of likeness. To primitive observation a whale must always be a great fish; it is shaped like a fish, and it swims in the water like a fish, therefore it is a fish. To perceive in the whale a mammal demands eyes of a wholly different focus. The point I

wish to make clear is, that the eye which has once clearly discerned the mammal in the whale can never, or with the greatest difficulty, get back to the infantile adjustment, and behold again only the huge fish of former seeing. Once leave your low-vaulted past and you can not return; you will never more, except in fancy—

> 'Have sight of Proteus rising from the sea;
> Or hear old Triton blow his wreathèd horn.'

"The term fancy, from this point of view, comes to seem, in a sense, inapplicable to the first vision of the childish mind. It rather denotes the conscious effort, more or less abortive, of mature intelligence to throw off or divest itself of its acquired insight, and revert for simple delight to a naïve and unsophisticated mode of regarding things. When a little child looks at a mask, it is a veritable face that he sees; there is no fancy about it. What we see is painted pasteboard; if we want a face we must fancy it. Or take the case of theatrical representations. In order to enter into and enjoy these, we must first dispossess ourselves of our sophisticated understanding, and try to forget and lose the thought of what they are in what they seem. This involves the exercise of fancy proper. To the little child such an effort is not necessary or even possible; he takes it all for reality. A half-grown boy, backward for his years, asked in perfect good faith where they buried all the people who were killed in the theatres!

"These considerations suggest a pedagogical question of much moment, as to how early and how far what is called nature study or science teaching should be allowed to replace with conceptions of natural law the primitive or mythical way of viewing and interpreting phenomena. Whether there is not danger of dimming and impairing by enforced disuse this natural vision before the later insight of understanding is ready to take its place? To mix a diet of literature and science, of imagination and fact, in the right proportions for a child is no mean art, though there are not wanting practitioners who are more than willing to undertake it.

"I have a few words to add in closing with reference to the position and character of child study in general. I have my doubts, as intimated heretofore, whether children can best be studied on the lines and by the methods of psychology, unless it be a psychology of a distinctly physiological type; and even this appears to me inadequate in taking so little account of the influence of the social medium, for a child out of the environment of society would be not unlike a fish out of water. This is made apparent on every page of our records.

"I do not see how certain problems of psychogenesis can find any satisfactory solution except through the procedure of physiological psychology; but when its methods of investigation have been fully applied, and the student has finished his work with the child, important and fundamental as that work is, there remains still the child as

a social embryo whose development is to be traced along new paths and under widely different conditions of observation and induction. I doubt if this task is to be handed over to the psychologist of the schools, for the reason that his training, however sound and broad, has been gained by dealing with phenomena that manifest themselves in a plane quite above and apart from childhood. The appeal of psychology is mainly, indeed almost exclusively, to adult consciousness, to the civilized and moralized man—a very different sort of being from the little child. Introspection, which is the main instrument and reliance in this study as ordinarily pursued, is manifestly inapplicable, if it be not an actual hindrance, in affording a true view of the mental condition of children. The bias of the introspective habit leads us inevitably to interpret their acts and deliverances in terms of our own conscious states, which are at every step so unlike those of children, quantitatively, if not always qualitatively, as to be positively misleading. As Rousseau says, 'we are always looking for the man in the child, without thinking what he was before he became a man.'

"Psychology as such has no alternative but to regard the child as a little man, a homunculus; whereas the mere fact of its immaturity and the shifting proportions which its facilities bear to each other in point of relative development at successive stages should suffice to put it, as an object of study, in a category of its own. Landor says, with characteristic insight, 'Children are not men or women; they are almost as different creatures, in many respects, as if they were never to be one or the other; they are as unlike as buds are unlike flowers, and almost as blossoms are unlike fruits.' What, for example, can any adult discover in himself that explains the savagery of the boy or the doll passion of the girl? Imagine the mental attitude of a butterfly that should attempt by introspection to account for the voraciousness of the larva of its own species! There is more than growth in the change from infancy to maturity; there is metamorphosis, and that often of a character little short of cataclysmal. The instability of childhood, the continual change of its center of gravity that results from rapid and many-sided development, is such as to defy explanation by any reference to what the grown man, psychologist or other, can find by searching the recesses of his own mind. Every process and step whereby he has come to be what he is, everything that has contributed to make him an adult, has carried him farther and farther away from the condition of childhood, and the door has been closed behind him at each stage of his advance.

"The child is a child chiefly in this, that with him racial instinct stands in the place of individual experience. His motives are impulsive and immediate. His mental vision is of short focus, narrow field, and high magnifying power. His view of things is all foreground, with no perspective of time, place, causality, or any of the relations of natural or logical consistency. He has but the faintest

idea of probability or contingency. In his world, as in the world of dreams, all things are possible, and one event is about as likely to happen as another. Hence perhaps his instinctive credulity, one of the most attractive of childish traits. There is little distinction or detachment between things present, things remembered, and things imagined. In place of a disciplined and consistent will, he possesses but the fragments or segments of physiological reflexes and instinctive impulses, combining almost at random and acting with capricious inconstancy. 'A boy's will is the wind's will.' In his feelings alone does the child, like the higher animals, make a near approach to the adult type, though still with marked differences. Sensitiveness in general, and fear in particular, are very prominent. There is much of the same instability and fluctuation, and, owing to lack of inhibitory power, a tendency to passionate excess. The general current of feeling sets strongly in the direction of the ego, though varied by occasional eddies of altruism that constitute much of the charm of early childhood. I need not say that this presentation is but a sketch, and makes no pretentions to literal accuracy or completeness."

* * * * * * *

"Children must be compared with children. And they should be studied chiefly in their gross and complex activities, not too analytically, and with constant reference to the social medium which is their natural element. As an object, a child should be held at a good focal distance; bring it too near the eye, and it becomes an unintelligible blur. Hence a certain clarified common sense, that takes account of the ensemble of conditions, is a better outfit for child study than a vision which the scientific habit may have rendered too intensive and microscopic. And in our interpretative comparisons, as has been hinted, it is better to direct the view downward than upward, even to the extent of classing children at first with savages or with animals, rather than with the fully developed man. I am glad to find this opinion supported by so high an authority as Professor Preyer, of Berlin, who, as a distinguished man of science, will not be suspected of inclining too much to the popular side. He says, in the preface to his 'Mental Development of the Child' (p. xvii, Brown's translation): 'Although the little child shows himself to the observer always without the least dissimulation—unveiled in both the literal and the figurative sense of the word—still there is great danger, with the anthropomorphic tendency of most people in their way of looking at things, that more will be attributed to the child than actually belongs to him. Moreover, knowledge of mankind is not of much help here at first, because everything which at a later period comes forth, obscurely or openly, is now present only in the germ. On the other hand, the observation of untrained animals, especially young ones, and the comparison of the observations made upon them with those made upon little children, have often been found by me very helpful toward

an understanding of children; and I hope from the completion of a comparative psychology, together with the inauguration of psychogenetic observations, more results than from the prosecution of earlier psychologies of a more speculative sort.'"

* * * * * * *

"Finally, it should ever be borne in mind that the study of children has wider and richer interests than those of psychology or pedagogy or any mere science. It touches 'the human heart by which we live.' It is worthy to stand, and it ought to stand, by itself. Its methods are for the most part yet to be devised, and the fullness of its outcome is not at present to be foretold or foreseen. I believe it holds the largest possibilities of delight, of increase of knowledge, and of practical utility. Yet its highest ideal, to my thinking, is simply enjoyment of childhood through sympathy and insight, without any ulterior purpose whatever."

CHAPTER XIV.

DISCUSSION OF EDUCATIONAL TOPICS BY PRESIDENT FRANCIS A. WALKER, OF THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY, WITH SOME ACCOUNT OF HIS LIFE.

The sudden death of Gen. Francis A. Walker removed from our midst one of the most influential and forceful men identified with educational interests. His personal attractions, scholarly attainments, versatile ability, and strong convictions brought him to honor in many departments of public and scientific activity.

The merest outline of his valued career is enough to indicate a man of rare powers. The principal events of his life are thus summarized in the Quarterly of the American Statistical Association March, 1897:

Gen. Francis A. Walker was born in Boston July 2, 1840. He was graduated at Amherst College in 1860, and entered upon the study of law. At the outbreak of the civil war he immediately enlisted and served during the larger portion of the war as an adjutant-general. At the close he was made brigadier-general by brevet.

After his military service, President Walker became instructor in Latin and Greek at Williston Seminary, and in 1868 was engaged upon the editorial staff of the Springfield Republican. In 1869 he was appointed by President Grant to take charge of the Bureau of Statistics, Treasury Department, Washington; and at the age of 30 (in 1870) he was made Superintendent of the Ninth Census. In 1872 he was Commissioner of Indian Affairs. From 1873 to 1881 he occupied the chair of political economy and history at the Sheffield Scientific School. In 1876 he was selected to be chief of the Bureau of Award of the Centennial Exposition. While at the Sheffield Scientific School he was a member of the school committee of New Haven and of the board of education of Connecticut, showing at this time the active interest in public school education which he never lost. He was a lecturer at Johns Hopkins University from 1877-1879. In 1878 he was called upon to represent the United States in the Monetary Conference at Paris. In 1878 he became a member of the National Academy of Sciences, and was vice-president of that body from 1890 until his death, and, in the absence of Dr. Gibbs, presided over its last meeting in November, 1896. When the time for taking the Tenth Census arrived, President Walker was appointed to superintend that work. The Census of 1880 was a greater undertaking than any preceding census, and more than twenty volumes was the outcome of the plan. This work established the reputation of President Walker in Europe as a statistician of the highest order.

General Walker became president of the Massachusetts Institute of Technology in 1881. In 1883 he was made a member of the Massachusetts Historical Society. From 1882-1890 he served as a member of the Massachusetts Board of Education, and as a member of the school committee of Boston from 1885-1888. In 1882 he

was elected president of the American Statistical Association, a position which he held until his death. President Walker became a member of the International Statistical Institute in 1885 (honorary member and president adjoint, 1893). From 1884–1890 he was chairman, Massachusetts Topographical Survey Commission. In 1882, 1883, and 1896 President Walker lectured at Harvard University. From 1885 to 1892 he served as president of the Economic Association. In 1888 he was made correspondent of the Central Statistical Commission of Belgium; in 1889 an officer of the French Legion of Honor, and in 1893 a correspondent of the Institute of France. He was president of the Massachusetts Military Historical Society from 1891. From 1892, he was vice-president of the American Society for the Promotion of Profit Sharing. From 1892–1894, President Walker served his native State as chairman of the Massachusetts Board of World's Fair Managers. He became a corresponding member of the British Association for the Advancement of Science in 1894. Besides serving Boston as a member of the school committee, President Walker was a member of the Art Commission from 1890, a trustee of the Museum of Fine Arts since 1887, member of the Park Commission from 1890 to 1896, and a trustee of the Public Library from May, 1896, until his death.

Of Dr. Walker's distinctive work as an educator, Dr. Davis R. Dewey writes as follows:[1]

There is a close association between his social and economic philosophy and the principles of education which he advocated. In education he stood for manual training, the kindergarten, and cooking and sewing schools for the mass; and for those who had the aptitude, technical training of a higher order, not only for its own sake as an educational factor, but as a conserver of the industrial and economic forces of the nation which now go to waste or wreck. Such training is a bulwark to the laborer in helping him to resist pressure and thus make competition a force working for good instead of for destruction. His views on the general educational value of manual and technical training have been repeated again and again in public addresses, and may be found briefly summarized in print in "A Plea for Industrial Education in the Public Schools" (Boston, 1887), and in an address delivered before the convocation of the State of New York, 1891, published in volume 4 of the Technology Quarterly.

Mr. Walker took an earnest interest in public-school education. During the period that he was connected with the Sheffield Scientific School he was a member of the Connecticut State Board of Education and of the municipal school committee of New Haven. When he came to Boston this interest in public school education was continued. He was a member of the State Board of Education of Massachusetts from 1882 to 1890. In this connection he was especially interested in making the normal schools truly professional. His influence was particularly felt in behalf of better laboratories, gymnasiums, and hand work. As a visitor at Wellesley College his influence was felt in the shaping of the scientific departments. He was a member of the Boston school committee from 1885 to 1887, and here made his spirited attack upon the teaching of arithmetic, and was instrumental in securing a reduction of the amount of time given to this study and a rationalizing of the instruction.

His chief glory, however, in education was his administration of the Massachusetts Institute of Technology, to which he was called in 1881. Over this he exercised a judicious, intelligent, and progressive administration. The wise plans of its founder, President Rogers, were developed and no error was made to check its growth. During this period of fifteen years the number of students increased from 302 to 1,198. Five new department courses have been added—electrical

[1] In the Review of Reviews, February, 1897.

engineering, chemical engineering, sanitary engineering, geology, and naval architecture. Instead of one building there are now four. There has been a wise recognition of the independent organization of the various departments, with, however, a beneficial coordination at all necessary points. He has supported a generous recognition of the study of language and literature, history and political science, as essential to a harmonious training of the engineer.

His work at the institute, however, should not be left without reference to his relations to the student body. These were indeed unique. Although giving no instruction, and never meeting the students in a class save possibly some two or three times a year when called upon for a special lecture, yet he knew, I think, every man of the graduating class each year, and could also address by name scores, if not hundreds, of other students of the school. He had their complete confidence and admiration. He never addressed the students on questions of discipline, for such questions did not arise under his administration, but every student with whom he came in contact—and scores saw him at one time and another in his office—felt an inspiration in personal contact, and by the unconscious influence of the manliness of their president.

President Walker's address on graduation day, in presenting diplomas, was brief, but always heard with eager interest. It was a message burdened with warm gratulations for the completion of a long course of laborious and honorable study and achievements. The student who heard it felt anew that he had been a worker, had lived with workers, and with earnest endeavor would go on through life a worker. It was honest and manly toil that counted.

Hon. Carroll D. Wright, in a commemorative address before the American Statistical Association, said:

It may be that we shall conclude that the most monumental work undertaken by President Walker was the administration of the affairs of the Massachusetts Institute of Technology. I have spoken of his equipment for that position. His experience at Williston and at Yale confirmed him in his estimate of a sound, practical education. Never ignoring the classics, always broad enough to appreciate and foster all that belongs to a college of the liberal arts, he, nevertheless, understood more thoroughly than most educators fifteen years ago the real necessity of the most complete scientific education. He therefore entered upon his duties in the institute with more than the ardor of an educator, for he had but little to do with teaching as such. His breadth of mind enabled him to understand the needs of the institute, and his great administrative abilities made him familiar at all times with all the features of the various curricula. His innovations were of the very greatest help to the young man seeking to equip himself for his life contests. He never believed in giving diplomas to men who had simply stayed the required time in the institution over which he presided; but when a young man was not competent to take the full course, or through ill-health or other adverse conditions was obliged to drop out of some of the departments, he gave him every opportunity to secure a special certificate in some one branch. By this means he has sent out into the world men often without a diploma to be sure, but thoroughly competent to take charge of work intrusted to them. We all know many of these young men,—we know their success; we know their loyalty to President Walker. He was their friend always, and at all times ready to aid with his advice and assist materially with his recommendations. While carrying the student roll of the institute from 302 to 1,198 during his incumbency of the presidency, he raised the standard of the school in like proportion. The graduates of the institute are found everywhere, and, so far as my own knowledge is concerned, always with the same result as to their standing and their efficiency.

It must be admitted that as an educator in the very highest sense President

Walker had no superior, and with that rare faculty of acquiring a personal relationship to each student his influence has never been surpassed, except it may be in the case of Mark Hopkins.

Dr. H. W. Tyler, one of Dr. Walker's associates in the institute, thus characterizes his distinctive power as an educational leader:

Some have won fame in education by profound research in the philosophy or history of pedagogics, some by assiduous labors in promoting the material welfare of schools or colleges, some by their skill in swaying the feelings and opinions of learned or legislative bodies. In none of these directions lay President Walker's greatest strength.

He was preeminently a leader, preeminently a leader of young men. His soldiers fought with his courage, his students studied with his insight, his associated teachers taught with his enthusiastic, vivifying zeal. He knew young men, he rejoiced in young men, and his knowledge was power over them and power in them. With most intimate sympathetic acquaintance with their qualities he always judged them with abounding charity. The earnest student, without ever exchanging a word with the president, felt for him the cordial confidence of a younger brother. Even the inveterate shirk, coming to him perhaps for censure, was uplifted by his generous optimism, gaining self-respect and becoming for the time, at least, as earnest as his fellows. With his nearer associates and friends he had that sunny cordiality which radiates light and warmth, but which so rarely survives the stress and strain of toilsome middle life.

The earnestness characteristic of institute students made President Walker's work with them peculiarly congenial, and he, on the other hand, enriched them by holding up earnestness as good in itself and as good for other purposes as well as for the primarily interested object of self-advancement. The institute was always to him "a place for men to work and not for boys to play," yet with their less serious side of life—their publications, their societies, and, notably, their athletics, none had keener sympathy than he. Young manhood was admirable to him in its physical as well as in its mental perfection.

His own intense activity and his insistence in earnest work have at times exposed him to misconception. It has been said that "the one intent and aim before him in his building up of the Institute of Technology was to make the course so vigorous that only the strongest could hope to complete it. It was an institution where men went to equip themselves for life work, not a hospital for the treatment of mental weaklings." The second sentence needs no confirmation, the first is altogether misleading. He was sensitive, almost to excess, on the subject of mental overwork by students. The faculty of the institute sets a definite, well-understood limit to the work to be required of any regular student in any term. Time and again he took pains not merely to enforce this rule, but to call the attention of overzealous teachers to its importance. Time and again he cautioned students against attempting even so much, if beyond their strength. Quality of of work, not quantity, was his requirement, as it was that of the faculty. The fact that institute students are thrown so fully on their own responsibility makes it possible for some to overwork, for others to neglect their work; he desired as little the former result as the latter.

As an administrator, President Walker sought always to lead rather than to drive, to win assent rather than to compel acquiescence. Perhaps because he had known war, he avoided even verbal antagonism in time of peace. His courage of opinion may not be questioned, but he knew and he taught others that much truth need not be hastily spoken. Neither in the faculty nor corporation of the institute was there lack of diversity of opinions and interests. His aim was always to secure harmonious action or else inaction until harmony should come.

Of teaching, in the strict sense of the word, he had in later years relatively little. The classes of his earlier time in Boston were fortunate in hearing his lectures in political economy, given to all regular students in their third year. Which one of them can forget, however helpless of memory as to theories of rent and wages, the affluence of illustration, the luminous exposition which, without sacrificing an iota of thoroughness or impartiality, removed mountains from the pathway of the faithful? To his temperament it was impossible to reduce economics to the metaphysical formalism of those who had made it a "dismal science." The "economic man" was to him not merely a vague abstraction, but a mischievous device for making the unreal have the semblance of the true.

If not a discoverer of new principles of education, or an exponent of a particular philosophy, of certain great fundamental principles he made enormous use.

The reaction of the new education against the old had no more marked, no more beneficent element than the great development of the study of things as distinguished from the study of books. Of the necessity, the dignity, the distinctly educational value of this study, President Walker was an unwearied champion. So, in his report of 1886, he says of the last graduating class of the Institute:

"Those years had been spent in the work, not of decoration, but of construction; not in polishing the surface, but in building up the substance of mind and character. Little time or thought had been expended in memorizing facts previously ascertained, or in rehearsing the opinions of others; but from the first day's exercise in the laboratory of general chemistry, on through all their course, these young men had been taught to see with their own eyes and think with their own minds, weighing, probing, analyzing, testing for themselves, the substances and appearances which formed the subjects of their study, until, through the development of their perceptive powers, through the formation of a habit of careful, discriminating, and minute observation, and through the exercise of the faculty of judgment, the least gifted of them had become capable, as evidenced by the severe test of our thesis requirement, of selecting a field of investigation, isolating the subject-matter, eliminating for the time everything alien or adventitious, providing all the conditions of a true experiment, and, through the application of approved tests, making an actual contribution to human knowledge. This is what we deem education in the best and fullest sense of that term."

THE RELATION OF MANUAL TRAINING TO CERTAIN MENTAL DEFECTS.[1]

The full title of my paper is manual training as an agent in the diagnosis and treatment of certain mental defects; but that statement exaggerates the importance of the paper, since what I shall have to say on the subject is merely in the nature of suggestion and inquiry. I have, in fact, no results to announce, no formed conclusions, even, to express. My mind has been drawn within the last few years to certain phenomena which appear to intimate the probability, first, that mental defects, seriously interfering with progress in study and with success in the affairs of life, may exist without being suspected by parents, teachers, or play and school mates; secondly, that such defects do in fact exist far more frequently than is popularly supposed. Brought to these conclusions, it has seemed to me that manual training or the practice of the mechanic arts as a means of instruction, while useful in the case of students of normal minds and of the best abilities, may have an additional and most important use as an agent, first for discovering, and then for treating, these defects. Let me ask your attention, some-

[1] Read by General Walker before the American Institute of Instruction, July 9, 1895.

what at length, to incidents which have suggested the probability that parent and teacher and play or school mate have often to do with wholly unsuspected defects of mental constitution and organization.

A few years ago I was called upon to act as the chairman of a committee to examine candidates for West Point, in one of the Congressional districts of Massachusetts. The thirteen candidates were subjected to the usual examination for physical soundness; and all satisfactorily passed the test. When we came, however, to the test of color blindness, a young man whom I had remarked as one of the most spirited, intelligent, and fine-looking of the group, advanced to the table and threw the skeins of colored worsted into groups so absurd as to seem actually impossible. One moment sufficed to show that he was wholly out of the competition and entirely ineligible for military service. Here was a young man, evidently of more than usual intelligence and ability, who had gone to the age of 17 or 18 without any suspicion on his own part that he had not the normal sense respecting color. His parents and the other members of his family from childhood had been accustomed to observe him in his dealings inside the house with colored objects; his playmates had doubtless on countless occasions made reference to the color of objects; and yet he had gone through all this, day after day and year after year, without having his suspicion excited that what they saw he did not see, and he had taken the trouble to prepare himself for an examination the results of which might affect his whole life without the faintest apprehension of his disability. I remember to have heard of a naval officer who went through the war and was afterwards discharged from the service for a long unsuspected color blindness which was almost total; yet for years he had been dealing with color signals and colored flags and ensigns. It is well known that the color tests introduced by boards of railroad commissioners in several States have resulted in throwing out not a few locomotive engineers of large experience who had never discovered or suspected their deficiencies.

Take another instance: A gentleman came to my office to introduce his son as an applicant for admission to the Institute of Technology. The young man had received an appointment to the Naval Academy at Annapolis; had passed the text-book examination; had passed the ordinary physical examination; had gone through the test for color blindness; and then it was found that an object which he could see distinctly with one eye at the distance of 27 feet had to be brought within 8 feet to be seen at all with the other eye. During all his childhood and boyhood he had never for a moment suspected the existence of this defect. Let me recite still another case: A lady of my acquaintance had very charitably taken into her household as a servant a young woman who was subject to severe nervous disorder. She could get employment under no ordinary circumstances, and the lady I referred to had undertaken to carry a part of her burden by employing her. After the lapse of some weeks this lady, who had often observed the servant very closely and curiously when engaged at her work, especially while sewing, broke out with an exclamation, "Jane, do you really see anything?" The girl looked up in great surprise. "Why, yes; I see perfectly well." Her mistress rejoined, "I do not believe that you see anything as we see it." An examination by an oculist followed, and it was ascertained that the girl's entire disorder proceeded from eyes that were simply a mass of defects and distortions. With treatment of her eyes the nervous affection in time ceased. I related this to one of the most distinguished medical men in New York, for many years a professor in the College of Physicians and Surgeons, who rejoined, "There are many such cases. My son, a captain in the United States Army, for years suffered the greatest agony from pains in his head and the back of his neck before he discovered that the whole trouble was due to defects of vision."

I might go on for a long time enumerating instances which have come under

my observation of a similar character; but what has been said will suffice to justify the inquiry whether, if such defects in such degrees can exist in respect to matters so objective and so completely open to observation and to examination, is it not probable that defects of mental constitution and organization of the gravest nature are found in every schoolroom and in every large family, and that much of what the parent or the teacher takes to be the result of indifference, or willfulness, or neglect is due to mental distortions, perversions, obliquities, lesions, and breaches of continuity, which have as distinct and decided an effect in preventing the proper and normal action of the child's mind upon what is sought to be presented to it as would the most objective deficiencies and injuries to the organs of sense. If parents and teachers and playmates and schoolmates can fail through years to see, or even to suspect, the existence of color blindness, for example, is it not possible, and even highly probable, that defects more deeply seated and of a more obscure character are the cause of no small part of the failures of the schoolroom?

Here is a child whose sense of hearing is seriously impaired. It is known that such deficiencies have existed for years without being suspected. In connection with the preparation of this paper a Boston physician has told me of a case recently coming under his knowledge where a young man had gradually become almost totally deaf through the slow process of the disease called adenoids, without his father, a practicing physician, suspecting the existence of the trouble until a late stage of the deafness had been reached. Now, in the case of such a child, whatever is said loudly and distinctly is heard. The moment the teacher's voice drops below a certain point, or her back is turned, or her speech becomes hurried and confused, the child loses all or a part of what is said. Something he makes out—perhaps by suggestion from what he has caught, perhaps by observations of the teacher's lips or gestures; some other thing he drops entirely; a third thing, still, he gets wrong. The result is partial failure in his work. He does not understand the true cause. His teacher does not suspect it. In the same way there must be instances of mental defects where a more than usual effort on the part of the teacher, a more than usual degree of attention on the part of the pupil, enables the current of thought to jump the broken wire and pass to its object; but any slackening of effort on the part of the teacher or of attention on the part of the pupil allows the current to become dispersed and to remain without effect.

It is not for a moment supposed that the thought above presented is not familiar to all students of the mind and all teachers of youth. The only contribution, if any, which I can hope to make is in urging the consideration that such mental defects as correspond to the defects in the organs of sense, of which illustrations have been given, are vastly more frequent than we have been accustomed to believe and demand greater attention from us in dealing with individual pupils; and secondly, that we have in manual training an agent for a diagnosis of some, at least, of these defects, and, though doubtless in a lower degree, for treating them. We go into an orthopedic hospital and our very souls are torn with the spectacle of distortion and perversion and deformity which we there witness on every hand, but we comfort ourselves by saying, "Thank God, it is only one child in a hundred who is thus afflicted." For my part, I believe that the cases of mental distortion, perversion, and deformity are far, far more frequent, and I can not help believing that it is to such unsuspected disabilities and infirmities of the pupil that we owe a very large part of the failures of the schoolroom, which pass for instances of heedlessness, willfulness, and even positively bad purpose. If I am wrong in this, as I easily may be, then I have occupied your valuable time and attention to no purpose; but the matter has so strongly forced itself upon my thought as to compel me to give utterance to it here and to ask this great body of practical teachers, as well as students of pedagogics, whether the subject is not deserving of special investigation and inquiry.

If, indeed, it is reasonable to believe that defects of mental constitution and organization corresponding to defects in the organs of sense do exist in regard to any large part of our school children, then it seems to me clear that we have in manual training so called—that is, the systematic practice of the mechanic arts in connection with drawing as a means of school instruction—a very important agent, at least, for their discovery.

If to the traditional studies we add manual training we have not only another test of application and capacity—a thing in itself of great importance, inasmuch as, by bringing in a new kind of test, we may largely correct the errors of the test afforded by text-book studies merely—but we have a test peculiarly suited to bring out the cause of any degree of failure in the performance of work. In the first place, the results of good or bad work with tools and upon materials can be measured, and gauged, and "sized up" with an accuracy which is not attainable in estimating the character of the work done in most of the traditional studies of the schoolroom. The teacher can see exactly in what degree the child has failed, and the child can see it for himself, which is far from being always the case with recitations and examinations. Not only so, but the teacher, as I believe, finds out much more closely the cause of failure in such work. If there is any tendency to misunderstand instructions and directions; if there are any defects in the child's organs of sense or any broken wires in his mind, a penetrating teacher ought to be able, by repeated experiment, to ascertain the fact. The objective character of the work, the closeness with which the results can be measured, and gauged, and criticised, and especially the aid derived by the teacher from the fact that the pupil is almost invariably desirous, and desirous in a high degree, of doing his shop work perfectly, all these combine, it appears to me, to make certain that a child will not pass through any very long course of study in a school where such exercises are systematically conducted without the discovery of any physical or mental defect which may exist. I do not mean to say that in all cases, or even in the majority of cases, the seat of the trouble will be precisely hit upon; but at least enough will be learned to give the pupil fair warning that he does suffer from some disability which he must make special effort to overcome. At least enough will be learned to put pupil and teacher in a better relation of mutual understanding and mutual respect.

Should the manual-training exercises disclose defects of mental constitution and organization, I believe that these same exercises may be used by the teacher most directly and beneficially in the treatment of such defects. Even though the teacher should not be so gifted as to be able to make the pupil's work discover the cause of total or partial failure, or of special weaknesses or infirmities, I still believe that the mere practice of the mechanic arts is the best possible regimen and gymnastic to which a mind in any degree falling off from the normal or suffering from any perversions or deformities can be subjected. What orthopedic surgery is to the body such, I believe, manual training in childhood is to the mind. I care comparatively little for its influences upon eye or hand. Its chief work, in my view, is educational; and in that educational work I place foremost its power of rectifying the mind itself, of straightening the crooked limb, so to speak, of strengthening the weak joint, of healing the lesion which, if not cured, will proceed to deep and irreparable injury. Not one of us but has seen seemingly hopeless cases of deformity and weakness in childhood completely cured by the splints, the massage, the fomentations, and the heroic surgery of the orthopedist. As I write I recall the images of schoolmates and playmates doomed apparently to hopeless suffering and weakness who are to-day, by reason of such treatment, straight, vigorous, and comely beyond the standard of their race. A benefit similar, at least in kind, can, I believe, be wrought in the case of many children who enter our schools suffering from inherited and acquired defects of mental constitution and organization by the judicious and intelligent use of the mechanic arts as educational

instruments. I am not here and now speaking for the more gifted and fortunate of our pupils, though entertaining the strong conviction that manual training properly applied in schools, freed from the crudities and errors incidental to the introduction of any new system, will prove of great educational benefit to the brightest and best of our scholars. I am speaking for a great body of children who, but for this new instrument of education in the hands of intelligent and skillful teachers, may go into life with serious mental defects uncorrected and even unsuspected; defects which will grow more serious and more hopeless with the progress of time and with experience of life.

THE EXTENSION OF TECHNICAL EDUCATION.[1]

The growth of scientific and technical schools on this continent during the past thirty years has savored of the marvelous. In part it has been due to the changed ideas and the transfigured ideals of the American people; in part to the recognized need of greater skill and more of scientific knowledge for the development of the natural resources of the continent and for the direction of its growing enterprises. In this movement of the age even the older institutions have been compelled profoundly to modify their traditional courses of study, substituting scientific and even technical instruction for much that was formerly deemed essential to a liberal education.

Of the reluctance, and even resistance, which this movement has encountered from many who deservedly held high places in the old educational order, I would not speak with harshness. The notion that scientific work was something essentially less fine and high and noble than the pursuit of rhetoric and philosophy, Latin and Greek, was deeply seated in the minds of the leading educators of America a generation ago. And it has not even yet wholly yielded to the demonstration offered by the admirable effects of the new education in training up young men to be as modest and earnest, as sincere, manly, and pure, as broad and appreciative as were the best products of the classical culture, and, withal, more exact and resolute and strong. We can hardly hope to see that inveterate prepossession altogether disappear from the minds of those who have entertained it. Probably these good men will have to be buried with more or less of their prejudices still wrapped about them; but from the new generation scientific and technical studies will encounter no such obstruction, will suffer no such disparagement.

Another objection which the new education has encountered is entitled to far more of consideration. This has arisen from the sincere conviction of many distinguished and earnest educators that the pursuit of science, especially where its technical applications are brought strongly out, loses much of that disinterestedness which they claim, and rightly claim, is of the very essence of education. For the spirit of this objection I entertain profound respect. I only differ from these honorable gentlemen in believing that the contemplated uses of science, whether in advancing the condition of mankind or even in promoting the ulterior usefulness, success, and pecuniary profit of the student of a technical profession, do not necessarily impair that disinterestedness which I fully concede is essential to the highest and truest education of the man. These gentlemen appear to me to have an altogether unnecessary fear of the usefulness of science. They entertain much of that dread of "Fruit" which Macaulay, in his famous essay on Bacon, doubtless with something of exaggeration, as his custom was, attributed to the old philosophers.

I am willing to admit that, in my humble judgment, many technical schools

[1] Remarks by General Walker at the dedication of the new science and engineering buildings of McGill University, Montreal.

have erred in addressing themselves too closely to the practical side of instruction; that they have in some degree neglected principles in the study of science, and have borne an undue weight upon mere knacks and labor-saving devices and technical methods. I believe that in doing this they have made a mistake, even from their own point of view, and with reference to the very objects they profess. Moreover, I am free to acknowledge that those who direct many technical schools have made a mistake in altogether, or nearly so, omitting from their curriculum philosophical as distinguished from scientific, liberal as distinguished from exact studies. Those technical schools will best accomplish their purposes of usefulness, alike to their students and to the State, which make more of the sciences than of the arts, more of principles than of their applications, and which offer to their pupils, in addition to the studies which will make them exact and strong, some of the studies and exercises which will help to render them at the same time broad and kind.

With only such a subordination of technical and scientific studies as is for the ultimate advantage of the technical professions themselves, and with such a complementing of scientific by philosophical studies as has been indicated, I believe that the work of the student in schools of technology is as fully entitled to be termed disinterested as that of a student in a classical college. In neither class of institutions can or ought the student to be unmindful that his personal success in life and his professional and social position are largely to depend upon the manner in which his work shall be done in college. All that can be asked in regard to any school is that there shall be zeal in study, delight in discovery, fidelity to the truth as it is discerned, high aims, and ambitions which have not sole or primary respect to material rewards. The strong desire to become a useful man, well equipped for life, capable of doing good work, respected and entitled to respect, constitutes no breach of disinterestedness in any sense of that word in which an educator would be justified in using it with commendation.

The practical uselessness for any immediate purpose of a given subject of study may be no reason why it should not be pursued; but, on the other hand, the high immediate usefulness of a subject of study furnishes no ground from which the educator of loftiest aims and purest ideals should regard it with contempt or distrust. In either case, the question of real import is in what spirit the study is pursued. The most distinguished French writer of to-day on matters of education, writing, too, in advocacy not of physical but of social science, has frankly paid his tribute to the disinterestedness of spirit and loftiness of motive which promote and direct scientific research, even in its most practical applications. "Let us," he says, "pass in review the great founders of modern science and the creators of industry, the Keplers and the Fultons, and we shall be struck by the idealistic and even Utopian tendency peculiar to them. They are, in their own way, dreamers, artists, poets, controlled by experience."

And if, leaving abstract reasoning, we turn to contemplate the manner in which the several professions are practiced in the community, I seem to find corroboration of the view that the study of science and its application to the arts of life do not tend to produce sordid character or to confine the man merely to material aims. Every profession has its black sheep and its doubtful practitioners; but, while frankly admitting that there are mercenary physicists and chemists for revenue only, I boldly challenge comparison between the scientific men of America, as a body, and its literary men or even its artists, in the respects of devotion to truth, of simple confidence in the right, of delight in good work for good work's sake, of indisposition to coin name and fame into money, of unwillingness to use one thing that is well done as a means of passing off upon the public three or four things that are ill done. I know the scientific men of America well, and I entertain a profound conviction that in sincerity, simplicity, fidelity, and generosity of character, in nobility of aims and earnestness of effort, in everything which

should be involved in the conception of disinterestedness, they are surpassed, if indeed they are approached, by no other body of men.

Let us, then, cheer on every enterprise for the extension of scientific and technical education, without any misgivings as to its effects upon the character and subsequent life of the young men of America, without any fear that they will be rendered sordid in spirit or low in their aims by reason of the practical usefulness of the studies to which they are called to apply themselves. There is a wonderful virtue in the exact sciences to make their students loyal, just-minded, clear-headed, and strong against temptation. Here no insidious tendencies to mere plausibility, to sophistry, and to self-delusion beset the young and the ambitious. The only success here is to be right. The only failure possible is to be wrong. To be brilliant in error here is only to make the fact of error more conspicuous and more ludicrous. Nothing but the truth, nothing less than the whole truth, this is the dominating spirit of the laboratory, which never withdraws its control over the student to keep him from the false path, which never intermits its inspiration as it urges him onward to the light.

COLLEGE ATHLETICS.[1]

I trust it will not be deemed beneath the dignity of this occasion that I should ask your attention to a few thoughts regarding college athletics. No theme is to-day of greater consequence to the colleges and universities of our land, whether as influencing school discipline or as affecting the standard of scholarship. Alike those who applaud and those who deprecate the growth of athletics must admit the importance of the subject.

The past ten years have witnessed a remarkable development in the direction indicated, which we may well pause to consider. The rising passion for athletics has carried all before it. Thus far, at least, there is no sign of reaction, or even of the exhaustion of the forward impulse. Honors in football, in baseball, and in rowing have come to be esteemed of equal value with honors in the classics, in philosophy, or in mathematics; and if the movement shall continue at the same rate it will soon be fairly a question whether the letters A. B. in the college degree stand more for bachelor of arts or for bachelor of athletics.

Among instructors and the governing bodies of our colleges there is a wide difference of sentiment on the subject. Some applaud, some doubt, some disapprove; others are simply dazed and know not what to think, or suspend all judgment waiting to see how much farther the rising tide will encroach upon the shore. In the larger community there is, perhaps, an even more pronounced divergence of opinion. Few college presidents or professors but see some good in the new movement and sympathize largely with the enthusiasm of their pupils. But there is a host of editors, preachers, and men of affairs in the outside world, and a host of parents and guardians more directly concerned, who are sure that it is all of evil; that the colleges are simply going wild over athletic sports, preparing the way for the downfall of the traditional system of education. To many of these it is a monstrous thing that large bodies of young men should give themselves up to contests of skill and strength, and that larger bodies still should find in these contests the chief interest of their college life.

Fairly to approach the subject, we need to consider the state of things which existed prior to the war of secession; in other words, to go back just one human generation, as a human generation is usually computed. In those days gymnastics held but a small, a very small, place in American colleges; while throughout the wider community there was almost no athleticism. The two most important exceptions to the latter statement were found in the occasionally outlawed and

[1] An address by General Walker before the Phi Beta Kappa Society, Alpha of Massachusetts at Cambridge, Mass.

always disreputable prize fight, generally with some international complication, genuine or manufactured, for the sake of stimulating public interest, and in a small amount of rather poor, unscientific boat racing. Almost no honor was then given to a young man because he was strong, swift, courageous, or enduring. The college hero of those days was apt to be a young man of towering forehead, from which the hair was carefully brushed backward and upward to give the full effect to his remarkable phrenological developments. His cheeks were pale, his digestion pretty certain to be bad. He was self-conscious, introspective, and indulged in moods as became a child of genius. He had yearnings and aspirations, and not infrequently mistook physical lassitude for intellectuality, and the gnawings of dyspepsia for spiritual cravings. He would have gravely distrusted his mission and his calling had he found himself at any time playing ball. He went through moral crises and mental fermentations which seemed to him tremendous. From the gloomy recesses of his ill-kept and unventilated room he periodically came forth to astound his fellow-students with poor imitations of Coleridge, De Quincey and Carlyle, or of Goethe in translation.

Not all college heroes of those days were of this familiar type. Sometimes they were thunderous orators, more Websterian than Webster, who could by a single effort lift themselves to the full height of perorations which in the senate or the forum are the culmination of great arguments and of many a passionate appeal. Sometimes, though more rarely, the college hero was a delightfully wicked fellow, who did, or at least affected to do, naughty things, wrote satirical verses, was supposed to know life, and in various ways exerted a baleful fascination over his fellow-students. But, however the type of the college hero might vary, speech-making, debating, or fine writing were the be-all and the end-all of college training, as in the world outside the colleges speech-making, debating, or fine writing were the sole recognized signs and proofs of greatness. Physical force, dexterity, and endurance, capacity for action, nerve, and will power went for little, or went for nothing, so far as public admiration was concerned. Statesmanship itself was perverted by eagerness to seek occasions for oratorical display. Men of business, men of affairs, men of prudence, moderation, and real ability were crowded out of our legislative halls by shrill-voiced declaimers who could catch the ear of a nation given over to the lust of words. "Sir," once said Daniel Webster, bending those tremendous brows upon a young man afterwards renowned among the great Attorney-Generals of the United States, "sir, the curse of this country has been its eloquent men."

What was the reason for this state of things regarding the college ideals of a generation ago, so strongly contrasted with what we see to-day? In part, bad physiology, or the absence of anything that could be called physiology, was responsible for it; but in greater part I believe it was due to the transcendentalism and sentimentalism of the last quarter of the eighteenth and the first quarter of the nineteenth century, which had created false and pernicious opinions concerning personal character and conduct. There was more than indifference, there was contempt for physical prowess. A man who was known to be specially gifted in this way was thereby disparaged in public estimation. If he were known to make much of it, he was more likely to be despised. It was taken for granted that he could not be good for anything else. Brains and brawn were supposed to be developed in inverse ratio. Affected notions about intellectuality and spirituality had almost complete control of the popular thought. The only things to be admired were mind and soul. "Mere bigness" was a favorite phrase of contempt. Strength was believed to be closely akin to brutality. Danger, positive danger, to spirituality, if not also to morality, lay in physical force and exuberant vitality. The same notions perverted the ideals of womanly grace and beauty. Robust vigor, a hearty appetite, and a ruddy complexion would have been deemed incom-

patible with the function of the heroine of a popular novel or a sentimental poem, or even with the part of a belle in society. Languor and pallor were attractive; delicacy of frame and limb was admired.

The set of notions referred to were doubtless closely connected with the political ideas of those days. It was an era of transcendentalism in politics. Political mechanism was disparaged. The philosophy of the age declared that a virtuous people would of themselves make a good government. On the other hand, it was impossible so to organize the public force as to give the people a government that should be better than themselves. The maxim "A stream can not rise higher than its source" was a conclusive answer to all pleas for the scientific treatment of political problems. There was an affectation of indifference toward size and numbers in national life. Quality, not quantity, was in the eyes of the men of those days the sole test of the worthiness and the greatness of a people. Mass went for nothing. "Mere bigness" was here, as in the case of the individual, a term of infinite contempt. I never shall forget the rebuke, not unkindly meant or harshly spoken, which I received from a distinguished leader of public thought for boasting in a boyish vein about the extent of my country and the greatness of its resources.

The indifference toward or the dislike of athletics a generation or two ago was also largely due to the religious ideas and feelings of the time. The body was but a shell, a prison in which the soul was confined, and against whose bars its aspirations continually beat and bruised themselves. In another image, the body was a wayside barn in which the weary pilgrim laid himself down to rest till break of day. The flesh was an incumbrance to the spirit, a clog, a burden, a snare. Men had been told to "keep the body under," and perchance this was thought to be an easier task if that body were small and weak.

I do not mean to be understood as asserting that in those days the mens sana in corpore sano was never spoken of, or that there was no formal teaching of the duty of preserving bodily health. Such precepts, however, could have little effect against general tendencies of thought and feeling; and even among the most intelligent teachers of those days there was manifest a strong dislike, a sharp shrinking from all dwelling upon the physical basis of life as savoring of materialism. As to acknowledging the relationship of man to the other orders of animals, that would have filled the pious mind with horror. The philosophy of the time had, indeed, to admit that the soul was in a degree conditioned as to its manifestations, and especially as to its influence upon others, by purely physical causes. But the soul itself was a thing transcendent, supernal, and self-sufficing, which when released from the clogs of flesh became at once as perfect, pure, free, and strong as if its tenement, while in residence here, had been more worthy of it.

All the notions referred to, so prevalent and so potent in at least this section of the United States forty or seventy years ago, have gone, and gone together. Other ideas better suited to inspire a progressive civilization have taken their place. In part this has been due to the decay of superstitions derived from primitive savagery, in part to the effects of positive teaching, in greater part still to further experience of life. Biology has done its share; political education has done its share; the war of secession wrought its appointed work in the same direction. The men of to-day are generally agreed that they are likely to live long enough to make it wise to think a hundred times how they shall live to once thinking how they shall die. The caravansary idea of existence has been abandoned. Man is not a pilgrim but a citizen. He is going to tarry nights enough to make it worth while to patch up the tenement and even to look into the drainage. This world is a place to work in: activity and development, not suffering or self-repression, its law.

The present generation has witnessed a wonderful diminution of spiritual self-consciousness. Better physiology, coinciding with some changes in popular ideals,

has driven away the notions about the flesh as an incumbrance, a clog, a burden, a snare. It is seen that morbid or even merely feeble conditions of body tend to generate delusions, selfishness, and susceptibility to the worst impulses. This is seen to be the case not the less because of the saintliness and the heroic constancy of a million sufferers from pain and infirmity. Hearty physical force may, indeed, consist with vicious desires, but it does not favor them. On the contrary, it does in a way and in a degree tend to diminish and to uproot them. Vicious desires are at their worst in feebleness and in morbid conditions of body. The sounder a man is, the stronger he is, the less—other things equal—is he subject to what is bad and degrading; the more pleasure does he take in what is natural, healthful, and elevating. To a perfectly sane man physically life itself becomes a joy. The relish for it does not need to be stimulated by the spices of vicious indulgence any more than a healthy appetite needs to be stimulated by the spices of the cuisine.

The sociological investigations into the causes and manifestations of crime, so actively in progress during the past few years, have added much to our knowledge of human nature in its self-respecting and law-abiding phases. The popular idea of the criminal once was that of a powerful brute, whose offenses against society resulted from an excess of physical vigor not counterbalanced by moral and intellectual forces. As a matter of fact, it is now known that the prisoners in our jails are, as a class, undersized and undervitalized creatures, often with a deficiency of coördination between their faculties, sometimes with a minimum of control over their own actions and little adaptability to social and industrial functions. In the remarkable, the truly admirable reformatory enterprise of Superintendent Brockway at Elmira, gymnastics, regulated exercise, and manual training perform a most important part.

In the revolution of thought regarding bodily development and physical prowess Mr. Beecher exerted a great influence. He it was who led off in favor of muscular Christianity. During the controversy on that subject which attracted so much attention just before the outbreak of our great war there was, we must admit, not a little of exaggeration on the part of the advocates of physical culture. Many wrote and spoke as if all evil was to be worked off in the gymnasium and on the race track; as if every vice of human nature would exude through the pores of the skin if only perspiration was sufficiently active and long enough maintained. But in spite of much that was crude and foolish, these men had got hold of a great truth, and they did not let go until they had drawn it out into the light. The war of secession, also, which has been adverted to, came in to produce a vast change in popular sentiments and ideals, as it showed how much nobler are strength of will, firmness of purpose, resolution to endure, and capacity for action than are the qualities of the speech maker and the fine writer, which the nation had once agreed chiefly to admire.

With this change of opinion regarding physical force and physical training in the individual has come a notable change in the political philosophy of the age. Larger experience of affairs has shown the folly of disregarding political mechanism. It is seen that it is hard enough to keep the balance of forces upon the right side, if every safeguard be adopted, every device used, and every means employed to give a preference to those who stand for order, decency, and honesty in the community. We are all now for making the devil fight with the sun in his eyes, instead of at his back, and with the advantage of the ground against him, instead of in his favor. We no longer with confidence hold that a virtuous people will necessarily have a good government. On the contrary, we recognize that a people virtuous above the average may, through a bad organization of the public forces, be made to act almost as if they were the most cowardly and dishonest of their kind. * * * It is true that the stream may not of itself rise higher than its source, but by machinery we can send a stream a good deal higher than its source,

and can make it do there more of vitally essential work than could all the waters of old ocean lying at their level. Instead of discarding political mechanism, therefore, the men of to-day believe in political machinery, like that of the Australian ballot system. They have learned that by means of it they can help the cause of righteousness, and at times turn the scale against the forces of evil. They not only believe in political machinery, they even believe in political machines, actual structures of wood and glass like the patent ballot box, as important agencies to defeat the baser elements of society.

Again, "mere bigness" has ceased to be a term of contempt as applied to nations. Power in a people has become a thing admired. It is felt that it is indeed a glorious thing to have a giant's strength, nor is it longer believed that the disposition to use strength tyrannously grows with the opportunity. The idea once prevalent that its possession leads to brutality and insolence has not been borne out by the history of our own people. As the United States have grown more powerful they have grown more peaceful. * * *

After this long and tedious statement of changes in the ideas and sentiments of our people in the several directions indicated, is it too much to say that we have, as a community, got down upon a sound, practical, sensible, worldly basis of life, much more promising for morality, for a steadily progressive civilization, for enduring enthusiasms—aye, for worthy aspirations and a true spirituality—than the unreal, morbid transcendentalism and sentimentalism of three, two, or even only one generation ago?

Among the many things, good or bad as people may esteem them, resulting from the changes in feelings, views, and ideals which have been indicated are two which especially concern colleges and college men: The first is the general disappearance, most fortunate as I esteem it, of the literary societies formerly so flourishing and the decay of oratory, declamation, and debate, which to many once made up the main interest of college life. The second is the rapid growth of athletics, in which immense honor is given to young men because they are strong, swift, enduring, and brave; in which the blood of the whole community is stirred by physical contests among the picked youth of the land as once it was only stirred by tales of battle. This last it is which has given me my subject to-day.

That the general introduction of gymnastics into colleges is desirable few will deny. Young men of the college age whose occupations are largely sedentary should be encouraged to undertake systematic and extended exercise in order to correct the faults of the study and recitation room, to expand their frames, and to promote an active circulation. Amherst is entitled to the high honor of being the first of the American colleges to make ample and suitable provision for students' needs in this respect. In 1861, under the presidency of Dr. Stearns, a gymnasium, large and well equipped according to the standard of those days, was placed upon the campus. Daily exercise was made compulsory upon students not excused for cause, and a certificated physician was made director of physical culture and lecturer on physiology and hygiene. Few colleges have followed Amherst in making exercise other than in the form of military drill compulsory; but fewer still now fail to afford their pupils opportunity for voluntary gymnastics to the top of their bent. The improvement wrought by these means in the physique of our college students does not need to be shown statistically. It is manifest to the eye of the most casual observer who remembers the former state of things. So far there is no ground of debate. Difference of opinion only exists with respect to the competitive sports and games which have grown up out of the newly awakened interest in physical prowess.

And here let me propose a distinction between gymnastics and athletics, which

will be carried through the remainder of this discussion. That distinction is not one based upon etymology, but has reference to current usage:

Gymnastics are for individual training and development, with health strongly in view. Athletics take the form of competition and contest; emulation is their moving spirit, glory the aim.

As thus distinguished in their primary objects, athletics differ from gymnastics in two respects: First, by specialization, as when a man chooses his line of work in athletics—whether that be pole vaulting, or hurdle racing, or rowing, or pitching in baseball, or playing a certain position in football—and thereafter devotes his energies to working himself up to the highest point of efficiency in that line; secondly, by excess in the amount of exercise over what would be required or would be performed without the introduction of the spirit of emulation. So great is this excess that it may not unfairly be said that athletics begin where gymnastics leave off.

The effects of specialization in athletics are too much a matter of detail to be entered upon here. Suffice it, in a word, to say that they are not unlike those of specialization in industry—good and evil being mingled, with, in general, the preponderance largely on the side of the good. Specialization affords to bodily exercise a more direct object and creates a far more intense and sustained interest. Moreover, for the best specialized work it is well known that at least a fair all-round development is almost always a necessary condition.

The excess of exercise in athletics over gymnastics, as we have defined these terms, is it of good or of evil? Is it a gain, or mere waste, or a positive injury? Gymnastics are a means to the end of health and vigor. Athletics become an end in themselves. With exceptions too inconsiderable to be enumerated, the athlete competing for championship honors takes more exercise, often far more exercise, than is required for health and strength with a view to the peaceful and industrial pursuits of life. Vital force is consumed, not created, by the final contests in which he engages, and not infrequently by the training to which he subjects himself in preparation for them. The consumption of vital force in athletics, if we contemplate young men who are fully grown or nearly so, may be considered as of two degrees: First, where vital force is consumed in competitive sports and games as it might be consumed in study or in the production of wealth, without impairing the constitution or diminishing the physical endowment upon the strength of which the subsequent work of life is to be done; secondly, where exercise is carried so far and such violent exertions are made that not merely is the current supply of vigor used up in this way, but the constitution is undermined and injuries are sustained or exhaustion induced, which result in leaving the man less healthful or less powerful through the remaining years of his life.

Of the severer forms of athletic competition and contest, which injuriously affect the constitution and permanently impair the vital force, but one thing can be said. They are evil and only evil. No earthly object, except the saving of others' lives or the defense of one's country, could justify such destructive exercises and exertions. I am disposed, however, to believe that there has been much of exaggeration in the public mind regarding this matter and that instances of permanent injury from athletics are fewer than popular rumor or maternal anxiety makes them to be. The life history of the leading football players of the past fifteen years, notwithstanding the frequency with which contusions, sprains, and even broken bones occur in the tremendous struggles of that mighty game, makes up a record of vitality and activity in the period succeeding graduation which proves that, despite the occasional outcries of the press, this form of athletic contest works little enduring injury among thoroughly trained competitors. The more serious accidents of football generally occur in the beginning of the season and among players who have not passed carefully through the hardening stages of practice. Boat racing is probably fraught with much more of real peril to its

participants; yet a distinguished English statistician, studying the life history of 320 "Oxford oars," has reached the conclusion that, even after making due allowance for the fact that these were all at the start picked men, this great body of athletes showed a vitality distinctly above the average. Yet when all has been said, it is still beyond question true that in the present intense interest in physical contests there is a real danger to be guarded against, especially among the younger and less experienced competitors.

Of those physical contests which result merely in the consumption at the time of current physical force which would otherwise, or might otherwise, be devoted to study, we can not dispose so confidently and summarily. To those who hold to the good old notion—the excellent, virtuous notion—that all young men go to college to make themselves scholars, it is, indeed, a great trial to have to contemplate a state of things in which no inconsiderable proportion of students treat scholarship as an object distinctly subordinate to gladiatorial prowess, and who really graduate, if they graduate at all, in athletics as a major, with classics, or mathematics, or philosophy, or something else as a minor, or perhaps we should say a minimum. Certainly this presents a view of college life which would have filled with horror the founders and early governors of our New England colleges. And it needs to be said at the outset, in dealing with this subject, that there are hosts of young men coming to college whose circumstances and means and views and plans of life are such that they can not afford to treat their educational privileges in this way; who if they "go into athletics," in the accepted sense of that phrase, will sacrifice the one opportunity offered them; whose presence with their classes means a degree of sacrifice and self-denial on the part of parents and friends which would make it little less than profanation to waste an hour of the time which has been purchased at such a price. And yet, with due consideration for the rights and interests of students like these, college athletics confessedly as an end in themselves are not wholly of evil. Several things have to be considered before we are fairly in a position to pass judgment upon them.

The least important thing that can be said in their favor is that they afford enjoyment to vast numbers throughout the land: yet, for one, I would not treat even this consideration as unworthy of respect. The college athletics of to-day do wonderfully light up the life of our people. The great recurring contests and the intermediate practice games and friendly competitions of the several teams give acute delight to a large and increasing constituency. This nation has long shown the painful need of more in the way of popular amusement, of more that shall call men in great throngs out into the open air, of more that shall arouse an interest in something besides money getting or professional preferment. In these respects college athletics have made an important contribution within the past few years. The marvelous rapidity with which football has spread and is still spreading throughout the Western and Southern States shows how eagerly it is welcomed as a relief to the monotony of life.

A stronger plea for college athletics is made when it is urged that they result in stimulating an interest in gymnastics among those students who do not engage in competitive contests, and also throughout the general community. The effect of this may easily be exaggerated. There is many a weak-kneed collegian who crawls out to witness the great baseball or football game of the year, looks on with intense delight, cheers the victors, if of his own side, as loudly as his limited lung capacity will permit, and then, when all is over, crawls back again to his room without so much as a conscious impulse to improve his own bodily condition. Yet it is certain that the cause indicated has an influence, and an influence not inconsiderable, for good. Admiration for manly prowess and the contemplation of fine physical development can not fail to secure a much wider cultivation of gymnastics than would take place without it.

But, again, it must be said that the favorite athletics of to-day are, in great

measure, such as call for more than mere strength and swiftness. They demand also steadiness of nerve, quickness of apprehension, coolness, resourcefulness, self-knowledge, self-reliance. Further still, they often demand of the contestants the ability to work with others, power of combination, readiness to subordinate individual impulses, selfish desires, and even personal credit to a common end. These are all qualities useful in any profession; in some professions they are of the highest value; and it can not be gainsaid that it is the normal effect of certain kinds of athletic sports to develop these qualities among the contestants, as well as to afford impressive examples to the minds of the spectators. So genuine does this advantage appear to me that were I superintendent of the Academy at West Point I should encourage the game of football among the cadets as a military exercise of no mean importance. It is the opinion of most educated Englishmen that the cultivation of this sport in the public schools of that country has had not a little to do with the courage, address, and energy with which the graduates of Rugby, Eton, and Harrow have made their way through dangers and over difficulties in all quarters of the globe.

The last consideration which I would adduce to show that what is sacrificed in athletics is not all lost is that in the competitive contests of our colleges something akin to patriotism and public spirit is developed, with results, on the whole, of good. It is true that young men often carry their manifestations of zeal and devotion to their colleges too far. Yet, both as counteracting the selfish, individualistic tendencies of the age and as an antidote to the nil admirari affectations of our older colleges, it is a good thing that the body of students should now and then be stirred to the very depths of their souls; that they should have something outside themselves to care for; that they should learn to love passionately, even if a little animosity toward rivals must mingle with their patriotic fervor; that they should at times palpitate with hope and fear and anxiety in the view of objects which can bring to them personally neither gain nor loss.

Of the special evils of college athletics as now cultivated, I do not purpose to speak at length. Some of those at present most clearly perceived are chiefly due to newness and rawness, and will of themselves disappear, in whole or in part, with time and further experience. Faults of method have yet to be eliminated; the traditions of the several games have yet to be created. For example, that regard for fair play, that respect for the rights of an opponent, that deference to the decisions of the umpire, so conspicuous in England, have there been the work of generations. They can not be built up in a day with us. Yet our people are wonderfully quick to learn, especially to learn everything that conduces to harmony and adjustment of claims; the American is eminently and preeminently a political animal; and nowhere in the world are great crowds so orderly, peaceable, and good-natured as here.

One of the first things which should receive the attention of all lovers of fair play is the complete abolition, once and for all, of the unsportsmanlike system of organized cheering by great bodies of collegians grouped together for the purpose, with chosen youths of peculiar gesticulatory graces and preeminent lung power to start the movement and "deacon off" the shouting. Such a line of conduct, thoughtlessly resorted to in the heat of partisanship, is unworthy of educated men. It is unfair to the visiting team, who, by all the laws of courtesy, are entitled to special consideration. How much more pleasing to the spectators, how much more creditable to the home college, if the stranger for the while within its gates were to be treated with something like the grace of antique chivalry!

Again, we may confidently expect that the machinery for carrying on sports and contests will undergo a steady improvement. We see a remarkable instance of the virtue of this in the appointment of the second umpire at football, which at once did away with certain tendencies that had threatened to make the game

impossible. Audiences, too, must be trained to appreciate the finer points, to applaud good work by whomsoever done, and to be as virtuous as a Greek chorus, to the end that the game may be played by the players and not by the spectators. The cooperation of alumni is also to be invoked to give wisdom, weight, and temper to the action of the undergraduate bodies. Not least—nay, perhaps hardest of all—faculties are to be educated, to avoid intermeddling and petty dictation on the one hand, and to sustain the claims of scholarship and enforce the right discipline of college on the other.

The last clause suggests one of the most important considerations related to the subject. Granting that something, and that not a little, of scholarship must be sacrificed if athletics are to be continued on anything approaching their present scale, may we yet believe that it is practicable to insist upon the requirement of at least respectable standing in the case of all who participate in intercollegiate contests. I believe that this can be done without interfering with the general movement, provided college faculties are true to themselves, fair, frank, and firm in dealing with the student bodies, and thoroughly honest in their treatment of the subject. I would not be understood to intimate that a certain amount of good sense would be out of place.

Perhaps it will not be taken amiss if I allude here to the results of my own observation in a sister university regarding which it has been my fortune to know more than I do concerning Harvard. At Yale, and especially in the scientific department, the faculty appear to me to have been highly successful in preventing a total sacrifice of scholarly standing to intercollegiate sports. But a small proportion of the champion athletes in that university, a smaller proportion still in the scientific school, have been men at or near the foot of their classes—the sort of men who have to be hounded, threatened, and repeatedly conditioned in order to keep them up to the mark. Not a few of them * * * have been high up on the roll of academic honor. I attribute this excellent result to the thoroughly good understanding between students and the faculty, to the absence of petty proscriptions and of all intermeddling as to details, and to the frankness with which the few positive requirements relating to the subject are stated and enforced.

I fear there is little in what has been here said to give comfort to those who distrust and dislike college athletics—little which intimates the opinion that the athleticism of to-day is only a reaction after the former total neglect of gymnastics, or a mere passing passion among our youth. But if we concede that these exercises and contests are to hold their place in American life, is there no stopping place, no point at which college authorities or the young men themselves, on their own motion, in their own discretion, for their own good, can say, "Thus far and no farther?"

I answer yes; there is such a natural stopping place. It is at the doors of the professional school. Among young men in the course of education, athletics should belong to the college stage; gymnastics to all stages. Whether this shall be done by regulation or be left to the operation of forces working upon the minds of the individuals concerned, I believe the result indicated will, in either case, be reached. Already the undergraduate principle is widely though irregularly recognized; and the movement of opinion is still clearly in progress in this direction. Here at Harvard you have seen many a renowned champion put off athletics as he entered the law school or the medical school. The rule should be made of universal application; and it will require but a little more of discussion, but a little higher education of student opinion, to bring this about. In and after the professional school, whether that be a school of law, of medicine, of divinity, or of technology, there should be no representative teams. The principle of competition and championship should be dropped. Individuals should continue at their

pleasure to play tennis or cricket or football with their classes, with private clubs, or in town and county matches; or if teams be formed in such schools they should not be regarded as carrying the honor of their institutions around with them. Such teams should not expect victory. They should play for exercise and for the fun of the thing, and should accept their inevitable beating with serenity and good nature, recognizing the fact that since they have taken up the serious work of professional preparation for life they no longer have the time or the strength at command to make and keep them champions.

There is one remaining question regarding the athleticism of to-day which I feel myself so little qualified to discuss that I did not even allude to it while enumerating the things that might be said in favor of competitive sports, or at least in deprecation of the hostile criticisms directed upon them, which, however, here in closing I would fain propose to your sounder judgment and keener thought.

It is whether the college athletics, which so many approve and so many condemn, have not after all a deeper significance—whether this remarkable outburst of enthusiasm for physical development and for the perfecting of the human body is not related, perhaps vitally and intimately, to the growth of a feeling for art in this new land of ours. No classical scholar will for a moment admit that it was an accidental coincidence that the nation of the Old World which pursued athletics with the most passionate eagerness, which showered honors upon the victor in running or in wrestling not inferior to those which it gave to the author of an accepted tragedy—that nation whose tribes came by long and perilous journeys over stormy seas to witness the great athletic competitions by the banks of the Alpheus or on the Crissæan plain—was the same nation which carried the arts, and especially the plastic arts, to the highest point of perfection ever attained.

If, indeed, there is believed to have been a vital connection between these seemingly diverse manifestations of Grecian life, who shall say that the remarkable enthusiasm for physical training and the intense interest in athletic contests which have been so suddenly developed in our country may not be clearly seen a generation hence to have accompanied, and that through no accidental association, the elevation of art to a far higher and nobler place than it had before occupied in the thoughts and affections of our people? The life class is the true school of the artist. The greatest of all who bear that name have been men who revered the human form, made it their chief study, and found in it their highest delight. If in truth this sublime passion is taking possession of the nation, who shall estimate at a price the worth of that inspiration? The vision of the Apollo may yet rise to the view of thousands out and up from the arena at Springfield, as erst it rose before the thronging multitudes of Olympia.

CHAPTER XV.

HORACE MANN AND THE GREAT REVIVAL OF THE AMERICAN COMMON SCHOOL, 1830–1850.

By A. D. MAYO, M. A., LL. D.

We have told elsewhere the "great and wondrous story" of the original inception of a system of universal education, organized, supported, and supervised by the people of New England, in the varied civic relations of district, town, colony, and State. We have shown that the New England colonists were able to achieve this, the most original of all their public achievements, because they represented that portion of the English people most deeply committed to the British idea of self-government and most profoundly impressed with the conviction that the foundations of a self-governing Commonwealth must be laid in the religion, morality, and intelligence of its citizens.

Besides this, until the close of the war of Independence, the people of New England were virtually of one mind on the subject of religion, strongly Calvinistic in creed and congregational in polity. Thus, although their original common school was what would be called, in our day, sectarian, it represented the almost universal public opinion of the time. What we now call "the religious question" in the common schools did not come up in New England until during the first half century of the Republic, and then was disposed of in its present fashion. On the other hand, all the colonies beyond the Berkshire hills and the Hudson River were, from the first, cosmopolitan in their national, social, and ecclesiastical composition. Hence, their effort to establish a system of universal education failed entirely during the colonial period, and only by slow and discouraging efforts through the first fifty years of the national life had they reached the table-land of a common school, essentially similar to that of Massachusetts and Connecticut, at the opening of the period now under consideration.

We have also seen why it was that the new Southwestern States, developed by the first great Western hegira from Virginia and the Carolinas, inherited the old British method of the organization of education adopted by the Atlantic Southern colonies, the college and academy, chiefly denominational, for the children of the well-to-do class, with a meager provision for the mass of the white people; and were thus left at the mercy of a widespread illiteracy, prolonged till a later date than this now under consideration. And even the new Northwest, with its magnificent outfit of public school lands backed by the national indorsement of universal education, was greatly baffled and hindered in placing on the ground its final school systems through the entire half century from 1780 to 1830 by circumstances inseparable from the establishment of new free States in a wilderness, during the opening years of the nineteenth century.

Thus, although it may be said in a large and popular way that by 1830 to 1845 the American common school had been established in the twelve Northern States

of the Union and that in the fourteen States then regarded as Southern a growing interest had been awakened and several cities, especially New Orleans, had established the American system, it is not remarkable that in the most progressive of these Commonwealths the public schools were far below the ideal of the advanced educators of the time. Indeed it was positively declared by such authorities as Horace Mann, Henry Barnard, and the leading common school reformers of New England, that in the States of Massachusetts and Connecticut there had been, for a considerable period, a steady decline in popular interest and the effective support of the people's university. And, although in the States beyond New England there had doubtless been a decided progress during the entire fifty years previous to 1830, a condition of school affairs prevailed through them all which left the opportunity for a general education of their people very uncertain, in many cases below the condition so deprecated by the foremost school men of New England.

In short, the original movement toward the present organization of universal education for a fit American citizenship, at the period now under consideration in the twelve Northern States, had won its first victory over the almost hopeless obstacles that for two hundred years from the earliest settlement of the colonies had stood up in opposition, and in the fourteen Southern States were to successfully resist its introduction for yet another almost half century, till 1870–1880. It is one thing to put into a printed constitution and even to organize into a new nationality for the loose union of thirteen contentious provinces a lofty ideal of democracy and quite another thing to incorporate the same ideal so that the people may stand before the world as a consistent democratic republic. Even more difficult has it been, first to gain the full consent of the whole American people to adopt the American system of universal education whose central institution and most powerful agency is the people's common school. It was almost a century from the organization of the National Government before one-half the States adopted it. And it is not strange that, even when all the Northern and several of the Southern States after more than two hundred and fifty years of colonial and national life had after a fashion accepted this as the final system of general education, in 1830, the farseeing educational statesmen of that period insisted that only through a great revival, reaching from the Atlantic to the valley of the Mississippi and penetrating to far-away New Orleans, could the common school system, then on the ground, be lifted up toward our present highly effective working agency for the making of good American citizenship.

It is not difficult to understand the reasons for this slow progress of the common school idea in the twelve Northern States before 1830, without imputing to their people an extraordinary indifference to universal education. It must be remembered that the original old-world immigrants to each of these colonies, British and Continental, had brought across the water the European system of education of two centuries ago. In that system a state church practically dominated and supervised the entire schooling of all classes of the subjects of these kingdoms and empires. Even the most progressive of these countries, Holland and Scotland, had not come to the New England idea of a system of universal education, established, supported, and supervised by the whole people. This system, despite all contradictions, still remains the most original and characteristic factor of the Puritan civilization of the New England colonies; the first time in human history when a whole people honestly and persistently undertook its own schooling for a self-governed State. The European ideal of industrial, social, and educational affairs, until the revolutionary epoch, remained virtually the ideal of several of the most powerful of these colonies, and only very slowly did the high walls of industrial and social caste and religious separation crumble before the persistent assault of the new American society. Still a majority of the original

Northern and some of the Southern States put into their first constitutions a recognition of the obligation of the Commonwealth to educate the whole people, and almost every new State added to the original thirteen, in the most solemn and positive manner pledged itself to the same duty.

But perhaps no people in history ever found itself in a position more critical, embarrassing, and absorbing than the 3,000,000, one-eighth negro slaves, that appeared before the world at the inauguration of George Washington as first President of the United States in 1789. The war of Independence had only yet half emancipated these colonies from the persistent hostility of the mother country. The irritation of this unfriendliness, aggravated by the disturbing influence of the French Revolution, kept the people of the United States stirred up until the close of the second war with Great Britain—1812–1815—finally brought to an end the long and dreary record of British intermeddling. The people of all the colonies had been left by the coming of peace in 1782 fearfully impoverished. The Government was bankrupt; was unable to pay its 250,000 veteran soldiers who had fought almost against hope through the seven years' war except in paper certificates of indebtedness, more nearly worthless every year. Then came on the excitement of the first immigration to the great new West and Southwest. Multitudes of the most adventurous and enterprising youth of the older colonies traversed the wild passes of the great Appalachian Mountain barrier or floated down the Ohio River to seek a home in the paradise toward the setting sun.

The population of the entire country was less than that of, at least, four of the present United States and was distributed over a region as extensive as Central Europe. There were few towns of considerable size, and by the lack of roads and the hardships of pioneer life the country was in no good condition for supporting a permanent system of education. The New England people had been left by the war in a state of religious demoralization which brought on the first revolt against the style of religious training that for two hundred years had gone unchallenged in the common schools. The towns in Massachusetts which, in their colonial estate, were able to support the town or grammar school, classical in its foundation, tributary to Harvard University, the precursor of the present free high school, by their changes in population, social and industrial affairs, had been forced to let it fall into neglect. In its place came up the New England academy, the child of the churches and private and municipal enterprise, which for half a century largely supplied the demand for the secondary education. As early as 1820, on the admission of Missouri to the Union, the contest over the extension of slavery was added to the already numerous exciting political questions that divided the people, culminating in the deeply absorbing events of the nullification period in 1830–1835. Then came in the long controversy on the financial policy of the General Government, in which the tariff and the banks arrayed the people in violent parties hostile to the verge of revolt. The northwestern and southwestern States, until 1815, were living under the constant peril of a most relentless and demoralizing savage warfare, always stimulated by the malignity of Great Britain through the Canadas. Up to 1780 intercourse between the different portions of the country was laborious, Ohio being practically farther from Connecticut than Japan from Massachusetts to-day.

Under these circumstances it is not remarkable that Connecticut, which before the Revolution had accomplished the virtual abolition of illiteracy and first of all the States had gathered a school fund, had been enticed into an organization in which the common school was so out of touch with the church that, for an entire generation, it steadily declined, and the sectarian academy and private school largely usurped its place. Rhode Island still held to the unflinching faith in individual freedom which had been so conspicuous in its settlement, and which became the great obstacle to organized effort for the common schooling of the

children. Maine was a corporate part of, and New Hampshire in many ways still a virtual annex to, Massachusetts until 1820. Vermont had been so involved in her original territorial controversy with New York and was still so inaccessible to the other States, being practically "out West," that there could be only a very gradual development of general education.

In Massachusetts the current of influence for a series of years seemed to be against the common school, whose establishment two centuries before had been her earliest title to historical renown. The old social British habit of sharp distinctions in society was still powerful, and the wealthy and educated classes seemed more and more inclined to withdraw their own children from the "common herd" into private and denominational seminaries. In 1837, when Horace Mann assumed the office of secretary of the new board of education, he found the majority of the cities and large towns paying a much greater proportional sum for the schooling of a minority of the children in private than for the training of the majority in public schools. The State was paying but $2.63 per capita for the education of five-sixths of the children in the public schools, a sum not larger than the Southern States are now contributing for their new system of public instruction. The only supervision of the public schools was by school committees, elected by the people of the 350 towns and few cities of the State. Not more than fifty or sixty towns even obeyed the laws for the guidance of this class of officials. The public school reports revealed this neglect of official control, a great deficiency in the teaching corps, a shameful condition of schoolhouses, and even in many of the larger towns of the State a dangerous indifference in the conduct of educational affairs.

But it would be doing an injustice to the people of New England to infer from this that interest in the general education of the coming generation had declined. There can be no doubt that in 1837 there was more good school keeping in all these States than ever before. The colleges had increased in number during the past fifty years, and were certainly better representatives of the higher education than at any former period. There was a fair amount of good work done in the 850 academical and private schools of Massachusetts and in the seminaries of Connecticut and the less progressive States. And although the common school in the rural districts had suffered from the habit of extreme separation, in which the people of every district, through an elected "prudential committee," retained a virtual control over the employment of teachers and the general conduct of the schools, yet in many of these towns there was a wholesome rivalry among these little obstinate district republics, which made for the welfare of the children.

The schools were taught, in the more advanced towns, by the best young men and women, the students in the colleges earning the means of pursuing their own education by winter vacation schoolmastering, and by the daughters of the leading families. The press had greatly improved since the days of the Revolutionary fathers. There were more libraries and more reading of good books as the years went on. The twelve years of the administration of Horace Mann, spite of his often disparaging estimate of popular culture, were distinguished by a great awakening of literary interest. It was the period of the rising influence of Emerson and the transcendental school of philosophy, the widespread interest in the romances of Sir Walter Scott and Dickens, and the birth years of our new American historical literature.

The sufficient cause of this general charge of the decadence of education by the common-school reformers in New England during the first fifty years of the Republic has been shown elsewhere. It was not the decline, but the general uplift of the national education to a higher plane, that brought forward the group of eminent educators, not always as workers in schools, but as public agitators, that made the great revival of 1830–1845 possible. Before the Massachusetts board of education under the lead of its great secretary had begun operations, there had

been a gradual awakening of the more thoughtful people of the New England States. In a number of schools, justly celebrated even by the severe tests of to-day, advanced methods of instruction were estimated at their full worth.

Men like Carter, Emerson, Barnard, and Brooks had appealed to the people, and the legislatures of all these States had been besieged by individual plans for important changes in the public-school laws. Essays at normal schools had been made in several quarters as a private venture. In Connecticut the conviction was steadily growing among the foremost people of the State that the public-school system must undergo a thorough revision. Even Rhode Island, last to come into the field, through the administration of Brown University by President Wayland, and the work of Kingsbury in his famous school for girls in Providence, and a rising up of the workingmen of the State, was preparing for her final effort at a later date. All things were getting in readiness for the revival of the common school, already beginning in the States of its birth, Connecticut and Massachusetts, and which was destined to spread like a great awakening light from State to State, from the seaboard in the Northeast to the valley of the Mississippi and to far-off New Orleans, the herald of a brighter day for the children of the nation.

The history of this revival of the American common school includes nearly the second half century of the national life, 1830–1870. First came the work of preparation, during the early years of the century, when the common school was accepted and set up in all the Northern States and the way prepared for the devoted band of educational reformers. This story has already been told. Second, the appearance on the stage in every Northern State, though everywhere under the leadership of a few prominent New England educators, of one of the most justly distinguished and successful groups of educational reformers known to any country in Christendom. This article will contain a series of sketches of some of the most prominent of these men, and an attempt to estimate the character of their work. Third, the subsequent reorganization of the old common school of the Eastern States into the graded school system of the present, from the rural district and city primary up through the grammar and free high school departments, to the State university with its final curriculum of moral, mental, artistic, and industrial training. This period extended till the breaking out of the civil war in 1860. The overwhelming interests of the next decade arrested the progress of all educational life in the country till 1870, when a second revival of universal education even more radical and significant in the entire Southern and Territorial sections of the restored Union set in, which is now "in full tide of successful experiment."

HORACE MANN AND THE REVIVAL OF THE COMMON SCHOOL IN MASSACHUSETTS.

On the 6th day of May, 1837, Horace Mann wrote in the third entry of a new diary: "Dined to-day with Edmund Dwight, esq., for the purpose of conferring with him on the late law authorizing the appointment of a board of education. Mr. Dwight had the civility, or the incivility (I do not doubt that his *motives* would place the act under the former category), to propose that *I* should be secretary of the board—a most responsible and important office, bearing more effectually, if well executed, upon the coming welfare of the State than any other office in it. For myself, I never had a sleeping nor a waking dream that I should ever think of myself, or be thought of by any other, in relation to that station. Query, therefore, could he have been sincere in his suggestion?"

On the 18th of the same month this "query" was answered by a written request from Governor Edward Everett that Mr. Dwight and himself should become members of the new board of education, with a renewal of the proposition that he would accept the office as secretary. The searching and pathetic words accom-

panying this entry in the journal suggest that Mr. Mann, in his capacity of president of the senate of Massachusetts, had been consulted in this matter, possibly had been one of the influential authors of that memorable statute from which dates one of the most notable reforms in popular education in the history of mankind. On his appointment as one of eight of the ten members of the board named by the governor, Mr. Mann writes: "This board, I believe, to be like a spring, almost imperceptible, flowing from the highest table-land, between oceans, which is destined to deepen and widen as it descends, diffusing fertility and beauty in its course, and nations shall dwell upon its banks. *It is the first great movement toward an organized system of common education, which shall at once be thorough and universal.*"

The Massachusetts board of education was established by an act of the legislature, passed on the 20th day of April, 1837. It was provided by this act that "the board shall consist of the governor and eight persons appointed by the governor, with the advice and consent of the council; each to hold office eight years from the time of his appointment, and one to retire each year in the order of his appointment; and the governor, with the advice and consent of the council, shall fill all vacancies in the board." The lieutenant-governor of the State was also a member of the board, ex officio.

It was characteristic of the political genius of the people of Massachusetts that this new agency, the State board of education, which remains to day the charter of its public-school system, contains no grant of power over State educational affairs save the appointment of its own secretary and the agents which are his staff, the general management of the State normal schools and teachers' institutes, with the appointment of their instructors and workers, the charge of the State school fund and the supervision of all educational institutions wholly supported by the Commonwealth. It can not touch the least district school or displace the humblest teacher. But, under a general indefinite authority of observation and suggestion extending to every school, and its duty of reporting to and consulting with the educational committee of the legislature, it has become perhaps the most influential permanent department of the State government, and has numbered among its more than one hundred members many of the most eminent men and, of late, several distinguished women of the Commonwealth, including more than twenty governors of the State. We find in this roll of illustrious names few professional teachers, but many men of national reputation in every profession and active calling. The original members of the board appointed by Governor Everett were James G. Carter, Emerson Davis, Edmund Dwight, Horace Mann, Edward A. Newton, Thomas Robbins, Jared Sparks, and George Hill. By his election as secretary of the board, on June 29, his acceptance of the office on June 30, and the beginning of his official life on July 1, Mr. Mann ceased to be a member of the board. His place was filled by the appointment of Robert Rantoul, jr., and the place of George Hill by Rev. George Putnam.

Never has the old Commonwealth been served by an official board containing more of signal personal ability and representing more fitly the varied interests of an American State than by this first board of education. Governor Edward Everett gave to it not only official recognition, but was himself one of the most earnest and influential workers during its first critical years. Mr. James G. Carter, probably more than any other man, had been the leader of the campaign of agitation which had at last brought the unwieldy and slow-moving legislature of Massachusetts to the important resolve to seriously undertake a radical reformation of the common-school system of the State. Rev. Emerson Davis afterwards became the first principal of the State Normal School at Westfield. Edmund Dwight, of Boston, contributed the $10,000, with a proviso that the State should duplicate the gift, that established the two original State normal schools for Mas-

sachusetts, at Lexington and Barre, the former the first in the United States. Robert Rantoul, jr., was already one of the foremost of the younger public men of the State, and his untimely death was little short of a public calamity. Rev. George Putnam was perhaps the most powerful New England preacher of his time, greatly interested in public education, and one of the inner board of control of Harvard University.

The election of the secretary, for by this name the State superintendent of the common schools of Massachusetts is known, is annual, by the board of education, and his duties are defined as follows: "The secretary shall, under the direction of the board, collect information of the actual condition and efficiency of the common schools and other means of popular education, and diffuse as widely as possible throughout every part of the Commonwealth information of the most approved and successful methods of arranging the studies and conducting the education of the young, to the end that all children in this Commonwealth who depend upon the common schools for instruction may have the best education which these schools can be made to impart."

The wisdom of this peculiar organization of the educational authorities of the State, which, in several of its features, has been copied in numerous cases at home and abroad, is vindicated by the fact that under it the most sacred and delicate public department of the Commonwealth is practically rescued from the excitements and perils of partisan politics. The members hold office for eight years, without salary, and the secretary can be retained as long as his services are regarded valuable. Under this organization the State, during the sixty-one years since the establishment of the board of education, has been served by its secretaries, always with fidelity and often with distinguished ability. Horace Mann was secretary for twelve years.

His successor was Rev. Barnas Sears, afterwards president of Brown University and the first agent of the Peabody education fund, who resigned at the close of a seven years' administration. Hon. George S. Boutwell held the office for five years, and only left it to begin the career of eminent statesmanship which has carried him through almost every high position in the gift of his own State and the nation. Joseph White was secretary for sixteen years, and left his mark on the body of admirable school legislation, of which he was probably the most influential author.

John W. Dickinson, second only to Horace Mann in valuable service, especially in his patient work for the elevation of the country schools of the State, assumed office in 1877 and retired in 1893. His administration of sixteen years left Massachusetts the only American Commonwealth in which instruction in industrial drawing, free schoolbooks and stationery, and a right to an education in a free high school are given to every child in the State. Ninety per cent of the school children of Massachusetts are now under effective district supervision, and almost every school district is in possession of a good library. Four additional State normal schools, a system of perpetual visitation, and numerous teachers' institutes, conducted by a corps of agents of the board of education, whereby every common school is brought under the eye of an educator of national reputation, with a score of excellent city training schools for teachers, attest the growing interest in this direction. Massachusetts now supports a common-school system in which in 1895 some 400,000 children and youth were instructed in 7,833 free schools by 11,714 teachers, 10,705 of whom are women, more than one-third of the entire number having received professional training in the State and city normal schools. The system is supported at an annual cost of $10,000,000—$19.48 for each child between the years of 5 and 15. The average wages of male teachers are $129.41 and of females $47.91 a month. The average length of the school year is eight and three-fourths months. Besides this, some 66,000 pupils are schooled in 99 academies and 359

private (chiefly Catholic parochial) schools, at a cost of $674,000. A dozen chartered colleges, with Harvard University at their head, and a great number of institutions for industrial, technical, and art instruction, business, music, and the various professions, are crowded with students from every portion of the country and were never so flourishing.

No State in Christendom to-day excels Massachusetts in the universal popular interest in education, the extended influence of its entire system of schools, and the educational characteristics of its numerous institutions for charity and the reformation of criminals. Indeed, in the prophetic words of her first great secretary, she is one of the "nations" that dwell rejoicing on the banks of that swelling river whose mountain spring, up in the highest table-land between oceans, is the board of education which sixty-one years ago began its modest existence with Horace Mann, a rising lawyer and politician of 41 years, already in broken health, almost penniless in fortune and bending under the great affliction from the recent death of his beloved wife, as its secretary.

He heard the call and, turning his back on the brilliant opportunity of a great professional and political career, stepped upward into the little office room in Boston, not under the statehouse dome, where for three years he lived and slept, working sixteen hours a day on a salary of $1,500, with no official assistance, that the common schools of his beloved Commonwealth, attended by what he called his "80,000 children," might be rescued from the decline into which they were falling.

Henceforth the great revival of the American common school—for twelve years, or until 1850—was more and more represented, not only to Massachusetts and New England but through the whole country, by one towering figure—the new secretary of the Massachusetts board of education, Horace Mann. And the more intelligently and broadly the educational affairs of that period are studied, the more clearly it appears that this man was one of the providential makers of American history.

No man is suddenly lifted out of the dust of obscurity to enduring reputation in any work of permanent value in a country like our own. Especially has every notable character in the educational development of the Republic gone through a severe apprenticeship before emerging upon the uplands of public leadership in any truly progressive movement for the schooling of the whole people. Horace Mann was no novice when, at the age of 41, already a commanding figure in the professional and public life of a State that does not readily give its allegiance to second-rate men, the unanimous voice of a group of men like Edward Everett, John Quincy Adams, William Ellery Channing, and Samuel G. Howe selected him as a leader in a conflict that was sure to absorb and finally exhaust the life of any man fit to bear the standard of reform into the confused wilderness that the common school of New England was becoming. It will explain a good deal that was not understood either by the contemporaries of Horace Mann or by many of the educational experts of to-day, if we trace his life from his birth up to middle age, when this great burden of honorable and perilous service was laid upon his shoulders.

Horace Mann was born in Franklin, a seacoast town in Massachusetts, on May 4, 1796, when the United States of America was but 8 years old. The town was named for Dr. Benjamin Franklin, who, it is said, intended to acknowledge the compliment by the gift of a church bell. But, on reflection, as he put it, "from what I have learned of the character of the people, I think they would prefer sense to sound," he gave the new town a library. Those little "town," "ladies'," "social," and ministers' libraries, located in the center of these New England towns, explain a great deal in the life of their foremost men and women in the first half century of the nation. Like so many another boy, hungry and thirsty

for knowledge, young Horace read the town library through and declared: "Had I the power, I would scatter libraries over the whole land, as the sower sows his wheat field."

His father, a worthy farmer, died when Horace was 13 years old; but the boy made the old place his home till 20. The mother was one of those sober, thoughtful, determined women of New England, who, under a laborious and almost a relentless routine of home life, carried the heart and will of a heroine. Those were the days of stern discipline in family and school, while the old-time mystery of high Calvinism was propounded by the Congregational Puritan minister, settled for life, in one sense, an ecclesiastical despot, yet an elected servant and representative, dependent for everything upon the good will of the most democratic community on earth. Dr. Emmons, a shining light in that tremendous dispensation, as Mr. Mann said, "through fifty-two years preached at and ruled the people of Franklin."

Until the age of 15 young Horace "had not a happy childhood." The family was on short rations, and the boy says of himself: "I believe in the rugged nursery of toil, but she nursed me too much." In winter he was shut indoors, braiding straw, by which he bought his own schoolbooks, and in summer was turned out to severe work on the farm. He wrote, later in life: "Train your children to work, but not too hard; and unless they are grossly lethargic, let them sleep as much as they will." But he did learn to work so that "industry became a second nature." Until 15 he only had from eight to ten weeks a year of the district schooling of the town. And it was a meager diet to which his hungry and thirsty soul was invited. If the secret of education is, as he declared, "the love of knowledge, not the love of books," he was, indeed, compelled to live on hard mental fare. The only schools he knew were a perpetual grind of memorizing schoolbooks that were often apparently written rather to conceal than to reveal the secrets even of the elementary "three r's." There was no attempt at oral teaching; even an intelligent explanation was often above the capacity of the village pedagogue. The discipline was the logical outcome of the preaching in the church; both a fair representative of the belief of the influential majority. "Sitting still," with an almost impossible obedience to the arbitrary will of the school master or mistress, and a correct verbatim recitation from a dry and dusty schoolbook, was the order of the day. Drawing, now a compulsory study in every common school in Massachusetts, was a forbidden amusement; generally discouraged by a smart rap on the knuckles of the budding artist, who had his revenge through that marvelous implement, the boy's jackknife, which left its imprint on every schoolroom bench till the temple of knowledge seemed almost in peril of being whittled out of existence; while every board fence, barn side, and granite bowlder was decorated by an uncouth and often indecent protest against the schoolroom tyranny.

It needed a mighty intensity of purpose behind a native longing for knowledge to carry such a sensitive, ambitious, and conscientious boy unharmed through the perilous years from 5 to 15. But he went through and came out unscathed. At 15 he says of himself: "I would as soon stick a pin in my flesh as through the pages of a book." There was no "dog-earing" or scribbling on the fly leaves of the few books he had earned by his winter's straw-braiding and summer toil. His reverence for knowledge was like a religion. "I looked on a young lady who had studied Latin as a sort of goddess." He came up in an era of coarse animal indulgence, neither drinking strong liquors, swearing, nor using tobacco. His "boyish castles in the air had reference to doing something for the benefit of mankind."

The great conflict of his early boyhood was the protest of his preternaturally awakened reason and keen sense of justice against the awful theology thundered over his head from the pulpit of Dr. Emmons. After untold torments, at the age of 12 he finally broke out from this terrible spell and henceforth thought and

felt his way up into a broad and catholic habit of thinking, though for many years in a maze of uncertainty, but never irreverent. It was well said, "His morality was what other people called religion." This "feeling after God lest haply he might find him" was all the more a trial from his intensely sensitive moral constitution. Horace Mann was to the last a Puritan of the Puritans; as he declares, "a man with a liberal creed and Calvinistic nerves." Like the majority of bright boys and girls of the day, he became a schoolmaster in the district school, where he taught several years before entering college and during his college vacations. He "fitted" for Brown University in six months, under a Mr. Barrett, apparently his first real teacher, and entered Brown as sophomore at the age of 20.

But his new Jordan was a weary road. His poverty was extreme. He writes to his sister: "A long time since my last ninepence bade farewell to its brethren." But he studied and got at money by all the ways best known to the struggling student of eighty years ago. He writes to the favorite sister: "In your next letter put in some sentences of mother's, just as she spoke them. Let her say something to me, even if it be a repetition of those old yarns—I mean if it be a repetition of the good motherly advice and direction, all about good character and proper behavior and straightforward, narrow-path conduct, such as young Timothy's in the primer." This terrible college toil, in which he won the highest honors of his class, graduating with a valedictory on "The progressive character of the human race," was lightened by his first love for the daughter of President Messer, whom he married and lost after the blessedness of two years of perfect home life. His only collision with the college authorities known to fame was his persistence in delivering an oration on a certain Fourth of July in the college chapel, captured and held for the Independence Day celebration by the students in the face and eyes of the faculty, who had closed the doors.

On graduating he entered the law office of Hon. J. J. Fiske, in the neighboring town of Wrentham, but was soon called back to Brown University as tutor in Latin and Greek. His best scholarship was in the humanities, although his love for science was a deep-seated and lifelong passion, with but small opportunity of satisfaction. From the university he went, in 1821, at the age of 25, to the law school at Litchfield, Conn., presided over by Judge Gould. Among the group of thirty students he was by common consent distinguished as "the best fellow and best wit, the best whist player, the best scholar, and the best lawyer in the school." He studied mental and moral philosophy, chiefly in the works of the Scotch metaphysicians, although in his later years stranded on the shoals of the popular fad of phrenology, largely through the influence of his friend Mr. George Combe, of Scotland, whose Destiny of Man and other works were certainly a great uplift to many of the earnest and thoughtful youth of the time. From the law school he passed on to the law office of Hon. James Richardson, of Dedham, Mass., and in 1823, at the age of 27, was admitted to the bar and began the practice of his profession in that town.

Living in Dedham for ten and in Boston for fourteen years, until the age of 41, Horace Mann was known as a successful and very able young lawyer and a rising politician. His exacting and almost fastidious sense of justice kept him aloof from any law case that did not commend itself to his conscience, and in consequence he won four of every five he undertook.

His unique faculty of public speech rapidly developed. In his arguments in court he always "endeavored to give each member of the jury something that could be quoted on his side in consultation." Few of our most effective American public speakers have achieved his remarkable power of condensing the gist of an argument, or compressing the central idea of a theme into one epigrammatic sentence. And although this faculty of brilliant and epigrammatic sentence making is doubtless, as in Lord Macaulay, a literary defect, yet it stood the great educator

well in hand while, for twenty-two years, he faced all comers, hurling at his throng of opponents his tremendous sentences, each like an explosive shell cast into the heart of a hostile camp.

In 1824 he attracted the attention of John Quincy Adams, then in the full splendor of his latter-day service in the House of Representatives in Congress, by a Fourth of July oration at Dedham. In 1827, at the age of 31, he was elected from Dedham to the legislature of the State. For the next ten years he was greatly absorbed by his political duties. He at once came to the front as the most conspicuous public leader in all matters concerning the higher interests of the Commonwealth. His first speech was a defense of religious liberty, probably in some connection with the law that still compelled every citizen of Massachusetts to pay a church tax, although with the privilege of deciding to what manner of church it should be appropriated, and the statute which up to a period near this had compelled every high official of the State to take oath to his belief in the prevailing theology. He also addressed and printed one of the first legislative speeches on the development of railroads made in the United States. He carried through the legislature the bill establishing the first State lunatic asylum in the country, at Worcester, Mass., under the efficient direction of Dr. Woodward. He was greatly interested in the institution for the deaf and dumb and blind then represented by Dr. Samuel G. Howe. He was the friend and adviser of Dorothea L. Dix, then entering on her memorable career as an angel of deliverance to the prisoner and the evangelist of peace and good will to all the oppressed, afflicted, and erring sons and daughters of men. His interest in the rising agitation for temperance was a part of his innermost life. He hated rum and tobacco with a perfect hatred, and it was always a trial for him to be charitable or even just to the best man who was addicted to their use.

During his residence at Dedham he married a daughter of President Messer, of Brown University, after years of patient waiting till he could pay his college debts and amass a respectable competence. The death of this admirable woman, after a perfect married life of two years, cast the afflicted husband into a shadow land of deep sorrow, spiritual uncertainty, and an almost ascetic habit of life. His brother failed in business and involved him in financial ruin. He removed to Boston in 1833, at the age of 37. During the four years following, already a man of commanding reputation in professional and public life, he lived, slept, and ate in his law office, sometimes unable to buy a dinner. He toiled sixteen hours a day. One of his earliest contributions to the public was his editorship, in connection with Judge Metcalf, of the revised statutes of the Commonwealth, in 1836. This year found him in the honorable position of president of the Massachusetts State senate, with every prospect of a political career that might land him in what may be regarded the most desirable position in the Republic, a permanent and prominent membership in the Senate of the United States. But the prodigious strain upon all the functions of life for twenty years had already broken the spring of a physical constitution of wonderful tenacity and power of rapid recuperation from dangerous prostration. At the age of 41 he seemed on the point of a final collapse of health. But above his sorely stricken, wearied, and failing body, he flamed out to all who knew him with that "radiant look" which to the end marked him as a revolving light flashing athwart the storm-swept sea of the tempestuous public life of sixty years ago.

All this time he was "laying up treasure in heaven" through the enthusiastic friendship of a group of men every one of whom became in his own way a marked character in national affairs. Dr. Samuel G. Howe he loved as a brother. Till the day of his death he made the clergy somewhat responsible for the suffering of his youth under the terrible ministry of old Dr. Emmons; but he sat gladly under the magnificent preaching of Father Taylor, for a generation the great Methodist

sailor-preacher and prophet of Boston. Of a sermon by Dr. William Ellery Channing he wrote: "It was as though his urn had been freshly filled from a fountain of everlasting love." Rev. Dr. Waterston and Rev. Samuel J. May were ministers after his own heart. Dr. Woodward and Dr. Todd, directors of the lunatic asylums at Worcester, Mass., and Hartford, Conn., were among his most honored friends. George Combe, who had come over from Scotland on a lecturing tour in the United States, was his lifelong correspondent and one of the few men who seem to have been largely influential in the development of his later philosophical and moral opinions. Charles Sumner was just emerging from his somewhat protracted lingering in the delights of scholarship and foreign travel into the great service in the cause of freedom that ended only with the close of the civil war. Jonathan Phillips, Edmund Dwight, and George Darrow were fine types of the eminent citizenship in which the New England cities have always been so rich—men of affairs who make leisure days and nights for the building of a city which shall be "set on a hill and not be hid." Of a lecture by Ralph Waldo Emerson he wrote: "It was to human life what Newton's Principia was to mathematics," although Dr. Walter Channing, who sat by his side, said it made his head ache. But, apart from the admiration and reverence for superiority everywhere, which is one of the most certain tests of genius, it is hardly possible that Horace Mann could ever have deeply sympathized with the new transcendental philosophy then in favor with a large section of the cultivated class of Boston, contemporary with the great revival for popular education and liberal thinking in religion of which Mann and Channing were the leaders.

But the time had come when it was becoming somewhat of a problem what should the State of Massachusetts do with such a character as Horace Mann. His deep, intense, almost fanatical sense of religion and morality; his relentless habit of forcing every man and every subject up to a moral standard; a moral policeman bringing the face of every prisoner under the glare of an electric light; his inveterate habit of "taking no thought for his life," according to the common habit of the vast majority of good men, so that the cause then on his mind and heart might have "free course, run, and be glorified;" his terrific power of public speech, joined with a singular magnetism for a large class of influential men, coupled with a knowledge of New England American common life surpassed by no man of that or any period, all marked him as one who in public affairs would be an unmanageable factor, not to be put aside. The great antislavery agitation that afterwards swept him aside from the grand work of his life into a Congressional career of six years had not yet come up into its later stage of war. What should be done with Horace Mann would be the most anxious thought of the few men and women who then represented what was so soon to become an "impending crisis" in national affairs.

But the appearance of such a man, so prominent that he can not be left out of sight of anybody when critical moral issues are involved, is in itself the most decisive proof that "a great and notable day of the Lord is at hand." This tremendous education of forty-one years was but a providential training for that educational statesmanship which assured his leadership in the revival of the American common school which was the fundamental condition of the salvation of the Union and the emergence of a new republic a generation later at the close of the civil war. His place was found when on July 1, 1837, Horace Mann assumed the duties of the board of education of Massachusetts and began a career of twenty-two years, memorable in the history of a State and nation. Here were a character and a career which have never been quite appreciated and never sufficiently honored by those who, by their position and culture, would be expected to hail his coming as "a man of God sent from heaven."

It may be thought a strange thing that this man, to whom apparently lay open

the most flattering prospect of a public and professional career, with peculiar opportunities for amassing wealth and the influence of high political station to patronize all the popular philanthropies, should have so easily turned his back upon them all and gone, like a lover to his wedding, to this untried and doubtful position. The salary was but $1,500 a year. He had not even the official aid of a clerk. He writes: "My task as yet seems incomparably great. I scarcely know where or in what manner to begin. I have, however, a faith, strong as prophecy, that much may be done." There is no reason to doubt his own statement that the proposition to take the office of secretary of the board of education when first made was a complete surprise. His thoughts were running in other channels, on the organizations for the relief of the deaf, dumb, blind, and insane, and the new temperance legislation. But when seriously considered, the idea of personal sacrifice does not seem to have occurred to him in view of the great opportunity of his life. He mentions with apparent surprise that, "with the exception of Dr. Channing, every man inquired about the salary and the honor of the station." The new movement of which he was the head had been born in a manger; "there was no room for it in the inn." The old Bulfinch statehouse had no corner where the greatest educational statesman of America could be given a chair and desk. He had a modest office on Tremont street, not far from the old burying grounds where lay the bones of the fathers of the Commonwealth, and there he lived and worked like a dray horse until his second marriage gave him a home.

His first official month of July and the early weeks of August were passed in a country retreat with a pile of books, thinking out a way to begin. He wrote a long letter to Edmund Dwight, on assuming the office, giving his impressions of his work. The first point he seems to have noticed in looking into the early records of education in the colonial period was that the movement proceeded entirely from the Massachusetts Bay colony, the broad-minded, college-bred, and well-nurtured men that founded Boston and the adjacent settlements. He says of the Plymouth colonists: "Compared with the contemporary legislation of the Massachusetts colony, the advantage is strongly in favor of the latter. Schools seem to have occupied very little of their attention. Learning was not a paramount object of their ambition." These Plymouth colonists were the people who came from an eleven years' residence in Holland, from which we are told that the New England common school originated. The fact is that the New England idea of education, from Harvard College down to the district school, was of purely British origin; it was the attempt of the most intelligent section of the British Liberal party in church and state to plant in the vigorous soil of a new world the university and free school from which they had drawn their own inspiration at home, with an extension of the opportunity to spread the feast of knowledge before the entire people of the colony. The fighting property of the new secretary, which to the end was the breath of his life, appears at once. "I will avail myself of the opportunity to recommend some improvements and generally *to apply a flesh brush to the backs of the people.*"

But the frame of mind in which he entered on his great enterprise irresistibly rises into a solemn and enthusiastic realm. "No man can apply himself to any worthy subject, either of thought or action, but he will forthwith find it developed into dimensions and relations of which he had no conception. How true is this of the all-comprehending subject of education." "On the part of introducing apparatus and substituting *real* for *verbal* knowledge, I must endeavor to effect a lodgment in the public mind." "*If error can only be conserved, how mighty will it grow of itself.*" "If I can be the means of ascertaining what is the best construction of schoolhouses, what are the best books, what is the best arrangement of studies, what are the best modes of instruction; if I can discover by what appliance and means a nonthinking, nonreflecting, nonspeaking child can most surely

be trained into a noble citizen, ready to contend for the right and to die for the right; if I can only obtain and diffuse through this State a few good ideas on these and similar subjects, may I not flatter myself that my ministry hath not been wholly in vain?" "Let the next generation be my client. Let me look forward to the children of the next generation rather than to the incorrigible men of this." "When I preach, I hope I shall not forget that, however near a true man may get to heaven, he still retains the main part of his relations to the earth." Good Jonathan Phillips sent him a present of $500. The salary fixed by the legislature, after deducting necessary expenses, left him $500 a year to live on. But he writes, with his peculiar humor that always carries an edge, "I will be revenged by doing more than $1,500 worth of good."

It is evident that Horace Mann went about this work to which he had been "called with an effectual calling" in no literary, scholarly way, or even according to the ordinary zeal of the educational spirit. It was to him, first of all, a work for the general elevation and inspiration of the people of the Commonwealth, and through them of the whole Republic concerning the relation of the younger third of the population to the general welfare, even the salvation of the State and nation from perils that no one saw more clearly than himself. It was evident to him that this was no mere professional labor of calling the attention of the people of Massachusetts and New England to the importance of a general enlightenment. Massachusetts and New England had never been indifferent to education, and from their earliest and feeblest beginnings as communities had cherished it as the apple of the eye. Nowhere in the world in 1830-1850 was there a reverence for distinguished ability and learning, a respect for high professional eminence, a habit of giving honor to superiority of character, genius, and large mental acquirements greater than was found among the "common folk" of these Commonwealths. Neither were Massachusetts or New England at that time destitute of great names. Webster and Channing and Everett and their like were at the height of their fame, and a group of younger celebrities in every profession were in training for the more exacting days that were sure to come. But in Massachusetts and New England educational affairs were in that peculiar state of transition where it was to be finally determined whether the aristocratic British ideal of a separate and higher culture for the well-born and well-off was to become the established order, or the whole people, as far as was possible, could be "nurtured" together for a republican citizenship that laid on every man, however great and good, the Christian obligation of being the servant of all and the brother of his kind.

In the days of colonial poverty and special disabilities, under the pressure of a chronic irritation from the heartless mother over the sea, it had been comparatively easy to keep the children and youth together in the little elementary and free grammar schools of the day. But now, after fifty years of national life, with the growth of a powerful cultivated and wealthy class, the first eruption of a great multitude of the humbler sort from Europe already coming in like a rising flood, the old British conflict of the "classes v. the masses" had once more arisen. The common schools had been permitted to fall into comparative neglect. The academies and colleges were regarded as the more appropriate places where the superior families should educate their children. The new transcendental philosophy had yet assumed no popular aspect, but rather encouraged its disciples to draw off into little communities or dwell apart in a scholarly and eccentric isolation that could easily nourish a proud conceit of superiority. The tremendous agitation among the churches inaugurated by Dr. Channing's famous discourse at the ordination of the Rev. Jared Sparks in a new independent church in Baltimore in 1819, and the secession of a hundred of the most powerful and influential of the old Puritan societies from the Congregational Evangelicism of the day,

were a fire in the bones of every little and great community in the State. The fury of political partisanship was at its highest pitch over the outbreak of the nullification movement in South Carolina, which was only compromised by springing upon the country the conflict of financial theories which we have with us today. There was imminent danger that unless the common school could be in some way lifted out of the ruts, reorganized in a form to meet the demands of the new time and the more cultivated and influential class, its teachers trained not to be ashamed to look in the face of a college professor or the reverend principal of a denominational academy, the country schoolhouse made the most instead of the least attractive place for the children and youth, the people of all sorts and conditions awakened as by a thunderstorm of remonstance, warning, and appeal to the peril of a society where a highly trained and ambitious minority should dominate an ignorant and quarrelsome majority, there was everything to be feared ahead.

No specialist, however earnest and eloquent, like Carter or Brooks; no scholar like Barnard, learned in all the wisdom of the educators of every land, no great teacher like Emerson, Kingsbury, or Wayland could now fill the scene. It was not so much a work of pedagogic enlightenment as of a high educational statesmanship, looking before and after, adapting the present conditions to the new possibilities of the Commonwealth and the nation, that under the modest title of secretary of the Massachusetts board of education challenged Horace Mann, woke him up to the first real consciousness of his own peculiar genius, revealed the possibilities of an original career, and summoned him as commander-in-chief of a great host to a conflict that would outlast his day, in which the victory could only be won when the Republic should be all free and the people of one mind go on to the making of the model nation of the earth.

His brief month of August in the country, buried in piles of documents, was all the preparation vouchsafed to the secretary for the beginning of his great work in the early days of autumn. Meanwhile the board of education had issued an address to the people of the State, inviting a series of popular conventions of educators and friends of the common school for general discussion, promoting a mutual acquaintance, obtaining information, and recommending some practical measures for advancing the good cause. The secretary was expected to attend all these meetings with the members of the board and as many of the distinguished men of the State of all professions as could be interested in the movement. Attention was called in this address to the condition of the schoolhouses, to the duties and compensation of school committees, the training of teachers, the establishment of district school libraries, and to a uniform series of schoolbooks as fit topics of discussion in these gatherings.

In addition to this method of ascertaining the actual condition of common-school affairs in the State, the secretary was directed to collate the reports of nearly 300 towns and cities on the state of education, containing the local details of the past year. This practice had been established a few years before, and a somewhat unsatisfactory series of abstracts had been prepared by the secretary of state. But Mr. Mann at once saw a great opportunity in this method of setting before the people the actual state of public education. Under his hands, after several months of incessant labor, his first Abstract of School Reports came forth, an intensely interesting volume, containing not only the statistics but the remarks and suggestions of the school committees. Its appearance was a cause of humiliation and hope—humiliation at the low average of popular education; hope in the great intelligence and good spirit displayed in many of the good suggestions of the local committees. The fact that there was now a commander in chief of the educational army awoke the same enthusiasm as the appointment of a Washington or a Grant to the command of a soldiery dispirited by feeble leadership

and constant defeat. At once the best men in every town, who had been discouraged by the almost hopeless condition of educational affairs, took heart and consented again to serve on school committees and give their best thought to their official duties and their experience to the preparation of their annual reports.

This series of abstracts, half a dozen in number, prepared with great care and incredible labor almost entirely by Mr. Mann, are among the most reliable educational documents in American official literature. The final result of this practice was the passage of a law requiring the school committee of every town and city in the State to issue an annual printed report to be forwarded to the State board of education. These reports, more than 300 in number, are now bound into stout volumes and offer to any inquirer into the present condition of school affairs the best means of obtaining information and of reading the words of a great variety of workers in every department of the schools in all sorts of communities. It was the most practical way of beginning the arduous work of the secretary, uncovering the actual status of the common school and popular education, and is now largely adopted by the school authorities of the country.

The preparation of this first abstract of reports seems to have suggested the fourfold method of dealing with the public to which Mr. Mann adhered with a marvelous and persistent industry and a complete success during his entire term of service of twelve years.

1. The abstract should be used as a method of placing before the public the annual condition of school affairs, not only what was being accomplished, but what the school committees, who were the motive power of the system, were thinking, feeling, and proposing to do.

2. In his own annual reports he began that elaborate discussion of the fundamentals of universal education which lifted this official communication out of the dry and dusty monotony of a formal public document to a positive addition to the literature of the American common school. These ten reports by the secretary followed each other in stately procession, each better than the last, the entire collection making one of the most notable series of powerful and suggestive writing on the general theme of public education ever given to any country. They became a model for this department of educational literature. Mr. Mann was followed in the West by the annual reports of the superintendent of St. Louis, Mo., and later Hon. William H. Ruffner, first State superintendent of schools in Virginia, followed in the same track and published a series of remarkable documents that declared him the Horace Mann of the new educational South.

3. For the wider dissemination of these reports, the publication of interesting information, and the discussion of methods of school organization, discipline, and instruction the Common School Journal was established and published ten years. It was edited by Mr. Mann as a personal contribution to education, in no way pretending to represent the opinions of the State board of education and inviting a wide range of discussion. It never paid its way as a pecuniary venture, and the editor received no return in money for the days and nights expended upon it. In this bimonthly journal is to be found a great deal of the secretary's most racy and suggestive writing, often going into the most homely details of school life, broaching ideas, methods, and ways and means that have become the commonplace of public-school administration. There is little at the present time in any department of our public instruction that was not suggested in that epigrammatic and intense style of his, which gave to every sentence the life and soul of his own eloquent spoken words.

4. But the spoken word was always a mighty power with Horace Mann. His lectures before the educational conventions that were at once called and grew up during his administration, published by order of the board, are still unrivaled in their combination of a broad and statesmanlike treatment of the entire subject,

with the most elaborate detail, splendor and pertinence of illustration, and skillful manipulation of the common facts of the everyday life of the child and the community by which he is environed. Theodore Parker said, "A New England audience must be treated to a good deal of logic and plenty of statistics to be greatly moved by a public speaker." The skeleton of every lecture delivered by Horace Mann, and every lecture or speech, whatever its title, had education for its theme, was just this masterly array of statistics, bound together by a relentless chain of logic. Yet all was clothed upon by a body of splendid rhetoric, enlivened by a grim humor that turned to his opponent a keen edge of satire, often lifted into the highest realm of eloquence by a religious, moral, and patriotic enthusiasm that declared him one of the greatest preachers of his day, the compeer if not the rival of Parker and Beecher as a true minister of the religion of love to God and man.

5. In addition to all these agencies, his correspondence was enormous in quantity and of a rare quality, which, even as it appears in the brief memoir prepared by his wife, only stimulates and exasperates the desire for more. In these letters he literally poured forth his innermost heart and soul and mind and strength into the listening ear of his correspondent. Our own large acquaintance with the elderly school men of the South has offered numerous interesting illustrations of this habit. A correspondence with gentlemen in New Orleans, La., was the occasion of sending Mr. A. J. Shaw, who had done reliable service in the legislature of Massachusetts at a critical period in the early administration of Mr. Mann, to that city and the establishment, with remarkable success, of the first system of public instruction in the Southwest. The third United States Commissioner of Education, Hon. N. H. R. Dawson, of Alabama, ascribed his early interest in public schools to the correspondence of Horace Mann with his father.

6. Most striking of all the methods of promoting the cause was the tremendous power of controversy, in which all the personal force, and sometimes the red-hot fire of the flaming indignation of his Puritan nature, raged like the eruption of a volcano. It was soon made evident to him that in undertaking to magnify the common school of his native Commonwealth he ran right into a hornet's nest of highly influential people, who at heart were thoroughly skeptical of American institutions, and preferred the British or Continental European schemes of education, not so much from their knowledge of any special superiority, but because they were the methods of an aristocratic or imperial régime. There was also an early demonstration of severe theological and ecclesiastical criticism, almost amounting to persecution, from one quarter on the charge of secularizing, and from the opposite direction of forcing sectarian religion into the schools. The great Catholic controversy on this matter had not yet taken form in Massachusetts. But there was enough of partisan religious jealousy of the influence of the State board of education and the rising power of its restless and imperious secretary. Later still, thirty-one grammar-school masters of Boston attacked him in solid column, evidently with an honest opinion that he was undermining the cause of sound education; but, perhaps, as the anticipation of a searching review of the condition of the grammar schools of the city, after an examination ordered by the public authorities, and conducted by experts like Dr. S. G. Howe, Judge Parsons, and Counselor Charles G. Loring.

In all these and similar cases he swept the field and overwhelmed his assailants by a combination of facts and figures, logic, sentiment, and satire heated red-hot and projected as from the crater of a volcano. In his subsequent career of six years in Congress, amid the fearful excitements of the period approaching the outbreak of the civil war, this habit became even more pronounced, and, as in his assault on Daniel Webster and his terrible wrestling match of controversy with Mr. Wendell Phillips, impaired his public influence and reacted on his temper and

And his work was not in vain. It is easier now than at that time to see this, obscured as it was by the toil and dust of a public service that was a perpetual conflict. His impatience, disgust, and despondency were often the inevitable result of his constant weariness. His health was always on the verge of a collapse, and he wrought at his great reports, abstracts, and lectures often in a feebleness of body and oppression of soul that might well have courted the relief of death. But despite all hindrances the grand work went steadily on. With the exception of the declaration of war by the thirty-one Boston grammar-school masters a few years later, after his report on the German schools and the teasing criticism of a portion of the religious press, he rarely was antagonized by one of the great men of his State or encountered any combination of the academical or college interest in any organized opposition. The legislature responded reasonably to his suggestions and during the first year of his administration passed a law increasing the compensation of school committees and enacted the statute establishing district-school libraries, which the secretary declared the most important law since the original enactment of 1647, which founded the American common school in the colony of Massachusetts Bay.

Before the first eventful year of his service had expired good Edmund Dwight made the gift of $10,000 to establish two State normal schools, on condition that the legislature would duplicate the same. On July 3, 1838, on Lexington Green, where "was fired the shot heard round the world," amid a pouring rain, half a dozen young people appeared, and under the lead of "Father Pierce," a distinguished teacher from Nantucket, organized the first State normal school in America. A second school, at Barre, in the interior of the State, was established later in the same year. Soon afterwards this school was removed to Westfield, in western Massachusetts, the Lexington normal to West Newton, and a third was set up at Bridgewater. The experiment of educating teachers in private academies subsidized by the State had already been tried at large expense with unsatisfactory results in New York. In New England several attempts to maintain a private normal school had only confirmed the most thoughtful educators of the day in the opinion that only in a system of professional schools supported by the State or a municipality, exclusively devoted to pedagogics and supplemented by institutes for teachers, was there any reliable assurance of elevating the standard of teaching in the people's schools. Mr. Mann persuaded his wealthy friends to give their money for the experiment of the teachers' institute and often spent liberally himself for the same cause. It appeared after his death that from his own small private means, assisted by Principal Pierce and other good friends of the cause, he really secured the establishment of these first schools and enabled them, under the skillful management of Pierce, May, Davis, and Tillinghast, to become a model for the country.

In 1839 the legislature enacted a law fixing a six months' term as the minimum of the district school through the Commonwealth. And still the great secretary goes toiling and thundering on, like a mighty express train laden with precious freight and brilliant schemes for the future. When Hon. Marcus Morton was finally chosen governor of the State by a majority of one vote and it appeared that the administration and the legislature were to be forced to a final decision whether the board of education and its restless secretary should be suppressed, he writes: "First, I will try to conquer; but if conquest is impossible, then I will try to bear." "Persevere, persevere, and so on, a thousand times, and ten thousand times ten thousand."

In 1839 the decisive conflict came. A majority of the committee on education in the house of representatives of the legislature reported a bill abolishing the board of education, the secretaryship, and the normal schools. An eccentric, enthusiastic, and magnetic popular leader, Rev. Alvin A. Dodge, of Hamilton, presented the argument against the whole idea and scheme of Horace Mann in a

written report and the accompanying speech. Fifty years later the same material was elaborated by his niece, the brilliant Gail Hamilton (Abigail Dodge), into a stout volume, written in wholesale disparagement of the American common school as reorganized by Horace Mann. This report was ably controverted by the minority of the committee, under the lead of Mr. A. I. Shaw, who afterwards established the common schools of New Orleans, La. The secretary himself took a full hand in the discussion after a fashion so effective that, some ten years ago, a member of the Massachusetts legislature was discovered voting steadily against every appropriation for the common schools of the State on the ground that fifty years before Horace Mann had so brought his father in the legislature under the flail of his terrible rhetoric and sarcasm that he could not do otherwise.

But the effort was a conspicuous failure, although it seems incredible to-day that 182 members of an intelligent legislative body in Massachusetts could have been induced to array themselves against the children's right to good schools, while 245 members stood up firmly for education. A subsequent attempt to transfer the duties of the board of education and the secretary's office, as in New York in 1822, to the secretary of state, met a similar fate and was the final defeat of the anti-common school faction in the Commonwealth. From that day, now fifty-nine years, the legislature of Massachusetts has stood firm as a rock on that question, always ready to adopt any proposition that could be shown to be a positive advance in the educational life of the State.

The new legislature of 1840 was more favorable than ever. It voted an appropriation of $6,000 a year for a term of years to the State normal schools. It also offered $15 a year to any school district that would duplicate the sum for a school library. The one mistake in this important movement, almost forced upon the management by the persistent assaults upon the board of education by certain clerical opponents of the secretary insisting that sectarian publications were included in the selection of books, was the attempt to prepare a library of 50 volumes written or adapted to the supposed wants of children.

But the reports of the secretary were everywhere read; 18,000 copies of one of them were reprinted in New York. They were translated into German and read with admiration in the highest educational circles abroad. He had created a new educational literature. Almost for the first time the reader of ordinary intelligence could listen with patience to an address on education or sit down to a public-school report with a feeling that he must read it through at the cost of an invasion of the small hours of the morning. The omnipresent secretary seemed to have his hand in every generous man's pocket in behalf of the good cause. Mr. Brimmer gave $1,500 to send a copy of the essay "School and schoolmaster" to every school district in the State. Meanwhile Mr. Mann was printing large editions of his own speeches at his own expense; never permitting himself to address a personal document at the cost of postage to the State; through his entire term of service maintaining a fastidious and almost fanatical ideal of official honesty and fidelity. Until his second marriage, to Miss Mary Peabody, a sister of the celebrated woman educator, Elizabeth Peabody, and of the accomplished wife of Nathaniel Hawthorne, he lived in his office after a fashion rather becoming the member of an ascetic religious order or a State prisoner on short rations than as became the dignity and comfort of the foremost popular educator in the world. During these twelve years of almost slavish toil and perpetual conflict with the enemies of the people's school, he paid off the indebtedness forced upon him by the failure of a relative. After his marriage he established a home in a mortgaged house in the then beautiful suburban village of West Newton. A great deal of his work was done there, for it was not till the administration of his successor, Dr. Barnas Sears, that it seems to have occurred to the legislature of Massachusetts to add to the office of the secretary that of State librarian, and to give the

chief of the vast educational interest of the Commonwealth a right to sit in an official chair under the statehouse dome.

The summer of 1843 completed the first half of the twelve years' service of Horace Mann as secretary of the Massachusetts board of education. On May 1 of that year he married Miss Mary Peabody. His health was again at one of those critical points that occurred with fatal periodicity during his entire educational career, the last twenty-two years of his life. He decided to visit Europe, at his own expense, ostensibly to recruit his wasted bodily vigor. But, as his friend Dr. S. G. Howe said, "His mind went of itself." The contemplated bridal tour abroad turned out one of the most laborious periods of work in his entire official life, a daily examination of the schools and public institutions of Great Britain and Germany, with his accomplished wife as an assistant. The work was complicated by his small speaking knowledge of the German and French languages, as he was compelled to depend largely on interpreters for conversation, although he could read public documents and general literature therein. But no man ever saw and felt more of what was about him than the secretary.

It would seem well at this point to "take account of stock" and try to ascertain what were the peculiar methods of operation by which Horace Mann awoke such a marvelous interest far beyond the borders of New England, and what practical results had so far been realized from his influence over school men and legislators. This seems to us the more important, since a full third of our own country is to-day in an educational situation in many ways resembling the condition of New England and the entire North sixty years ago. In the sixteen States of the South the common school has been established within the swift thirty years since the close of the civil war in a manner that has challenged the admiration of the educational public at home and abroad. But to-day the South finds itself at a most important crisis of its educational history. In New England and the North in 1830–1850 enough had been done to settle the question that these States had finally indorsed the American system of common schools as the permanent method of training their entire population for American citizenship. But as Horace Mann, in 1837, found the common-school system of Massachusetts entirely inadequate to meet the demand of that early day, so the foremost educators of the Southern States are now asking, How shall the new common school, through a region as large as Central Europe, inhabited by 25,000,000 people, three-fourths of whom are still living in a sparsely settled rural country, with little surplus of earnings or savings to spare, with open and secret enemies of popular education on every hand, already the legislatures of several States showing signs of a reactionary policy, be taken in hand and lifted up to a state even approaching that of New England and the North, so that the entire benefit of this method of public education may be realized? There is no better answer to this question than to study attentively the record of the ideas, plans, and policy of Horace Mann during the first six years of his administration. During that period he had not only made manifest the spirit he was of and what should be the manner of man to lead a great revival of popular education, but he had shown by what minute, painstaking, and gradual steps, against what vexatious, even exasperating, opposition, in constant peril of fatal reactions, the great and good work not only went on, but obtained that momentum on which every great public tendency in a country like ours must finally rely for permanent success through a long period of years.

We can easily see that the task set to himself by the secretary was twofold. First, a great revival of attention and enthusiastic interest in the common school idea must be awakened in all classes; not alone in the lower stratum of population which was constitutionally indifferent or hostile, but among the educated, wealthy, and influential class whose sympathies were half alienated from the

people's university and seemed on the point of falling back on the old British way of a separate scheme of culture for their own families. Second, as this campaign of education should proceed, he labored to the end that the attention and interest of the lawmaking power should be awakened and concentrated up to the point of a revision of the school laws of the Commonwealth that amounted to a complete reorganization of the present system.

And this, from 1830 to 1850, was a work of peculiar delicacy and difficulty; for the intense individuality of the New England character and the peculiar organization of its public township life, with a constitutional abhorrence of the concentration of power, made this work of reorganization almost "a war of posts," each of 350 obstinate towns and cities to be besieged and captured in succession. And the deepest depth of this tendency had been reached by the law which made each one of some 3,000 school districts a corporation, practically all-powerful to determine the vital condition of its school. To put on the ground an organization, not at once, but by patient working through a generation, that would "smoke out" these little district school communities from "the hiding place of their power" might have taxed the executive genius of a far less impatient reformer than Horace Mann. But by the wonderful combination of faculties in which no American educator has been his equal the great revival was set in motion, the machinery was carefully manipulated, and the tracks of influence surveyed by which the good work went on with never a serious backset from the last year of his service to the present day.

We have already seen with what an almost incredible energy of purpose, fertility of resource, and unconquerable patience he organized the forces of the great revival. He was master of half a dozen separate methods of appeal to different classes of the people. By attracting to his cause the men of the highest ability and culture most held in esteem by the whole people of the Commonwealth, by his own Common School Journal and the constant use of the press, by turning the new lecture system into an agency of educational reform through the village lyceum which already blazed with the discussion of common-school affairs in every town in the State, was the public not only awakened but kept more alive year by year. Never was a Commonwealth in Christendom more thoroughly besieged, bombarded, overwhelmed as by a cyclone of agitation than Massachusetts during the twelve years of the administration of Horace Mann. The office of secretary of the board of education was like a central public school room, agitating the people, continually reporting and suggesting methods of reform to the legislature, yet with no legal power to act. But when the first Massachusetts board of education called Horace Mann to his place, its members knew just what they were about. Here was a man who not only would faithfully perform the legal duties of his office to the very letter, but, above and beyond, would magnify the office itself and tower aloft, shining everywhere, make himself the vital public center of every organization, a tower of flame in the far-away East, seen from every corner of the Republic.

For twelve years he so dominated the State, so compelled everybody to follow or fight him, that it required ten years of the comparatively mild administration of his successors, Sears and Boutwell, for a rest before the vigorous administration of Joseph White and the long and splendid service of John W. Dickinson could bring the educational affairs of the State to their present high position. As in Southey's poem, "The Curse of Kehama," the Prince of Darkness is represented as storming a city over a score of avenues from every point of the compass, so the opponent of Horace Mann knew not whither to go, for he was met by some new incarnation of his terrible energy at every turn of every road.

But the progress of actual reform was not at any such rate of velocity. In fact, we have seen that the second year of his administration was largely occupied in manipulating the legislature to resist a desperate effort to repeal the entire system

and abolish the secretary himself. But this victory was final, and one measure after another was carried, each a foundation stone in the reorganized common school.

1. First of all, the board, under the leadership of its secretary, ordered an abstract of the common-school reports of all the towns and cities of the Commonwealth made for the information of the people. It was already the duty of the secretary of state to do this work, but the secretary of the board relieved that official of his duty, and year by year launched upon the public a series of "Abstracts" that opened the dullest eyes and awakened the apprehensions of the most confident concerning the true state of educational affairs. It seemed as if nothing was right and as if each department of public education was a little worse off than its neighbor. The board called attention to the disgraceful condition of schoolhouses in so many of the districts that it seemed a common evil; to the lack of preparation by teachers, and the consequent poverty of the instruction; to the uncertainty of school attendance, one-third of the children between 5 and 15 being constantly out of school; to the chronic neglect of school committees to attend to their duty of the examination of teachers, visitation of schools, and superintendence of schoolbooks, of which three hundred sorts were in use in the State; to the irresponsible and often half-barbarous methods of discipline, including corporal punishment as a steady régime. All these things revealed a confirmed common-school habit, by the indifference of one and the neglect and opposition of another section of the people, who should work together for the common good of the children and the State.

The first year was spent largely by the secretary in visits through the State, chiefly at his own expense, addressing conventions, often little squads of hearers, but all the time getting at the influential people of every community, devising ways and means and methods of work. Especially did he work upon the real motive power of the whole machine, the town school committee. This was the only system of school supervision on the ground, a body of three, or some multiple of three, men elected in town meeting or in cities by popular vote, working with no adequate compensation, on whom was cast the delicate and laborious duties included in the present elaborate scheme of city and district superintendency. By legislative enactment he caused the salary of these officials to be raised, and labored with all his might to overthrow the mischievous arrangement of separate districts, of which he said: "I consider the law of 1789, authorizing towns to divide themselves into districts, the most unfortunate law on the subject of common schools ever enacted in the State." His whole contention was to gather up this wide, extended, shapeless tangle of a district school system, responsible to nobody out of eyeshot, jealous as death of town authority, and rebellious of State control, into a compact body, not by the European fashion of the imposition of a power from above, but by the intelligent control of the whole people. For twelve years Horace Mann was virtually superintendent of schools in every town and city of the State; never more so than when the thirty-one grammar schoolmasters of Boston organized a teachers' rebellion and were thrashed into subjection by their mighty master, representing the outraged public opinion of the city and State. But it was not till the power of his great personality was removed in 1850 that school superintendency even of Boston was enacted by law. And until 1859 the district system maintained a losing fight against being merged into the town of which it was a part. To-day nine-tenths of the children of the State are under a local or district supervision, besides enjoying the constant inspection and advice of the expert agents of the State board of education.

2. The State school fund had already been created on paper, in 1834, with the proviso that it be raised to $1,000,000 from the sale of public lands in Maine and other sources. The board of education was now intrusted with the care and dis-

or were able to get three summer or two or three winter months in public schools. In 1839 the law was passed which required a six-months school, continuous or divided into two terms, as a minimum of free public education in every district. The same law provided for a female assistant to every school of more than fifty pupils. But the teachers were still elected by the "prudential committees" of the separate districts, until in 1844 this power was partially, as it was later fully, restored to the school committees. The statute compelling the teacher to file a certificate of examination before receiving his salary corrected an abuse that will everywhere prevail while the office of rural teacher is at the mercy of a personal favoritism most injurious to the public welfare. Already, in 1827, the excellent law making the establishment of a free English high school compulsory on every town of 500 families (2,500 people) and of a classical high school in every town of 4,000 people had been placed on the statute book. Massachusetts is still the only American Commonwealth that in this way makes the secondary education now compulsory on all her population, a fashion which has not only been of immense value to the State, but has so advanced the reputation of Massachusetts in the upper side of public and private instruction that the income from the tuition and living of persons coming to the State to attend the secondary, higher, and professional schools is to-day many fold the outlay of the half million expended on the 30,000 free high-school pupils at home. To-day every child in Massachusetts has the right to forty weeks a year, for three or four years, in a free English or classical high school.

5. In 1837, although by law the school committees were authorized to select the text-books and arrange the courses of study in all the public schools, the statute "was more honored in the breach than in the observance." The secretary found three hundred different sets of schoolbooks in use in the State. He labored with all his might to introduce order in this realm of dire confusion and did succeed beyond expectation. He brought in not only the present arrangement of a reasonable uniformity of text-books, but encouraged the introduction of a better quality. Some of these which came up at this date under his encouragement are still among the best in any language. To-day all text-books and material for school work are free to every child of the State. The books are purchased by the school authorities and loaned to the children, who are thereby taught the valuable lesson that came to young Horace Mann by instinct, "that he would as soon stick a pin into his own flesh as into a page of a book." His writings are full of the advocacy of oral and personal instruction, and long before his visit to Germany he had suggested nearly all the improved methods of approaching the mind of the child, with the emphatic indorsement of the woman teacher in elementary instruction, that have so mightily changed the aspect of the primary schoolroom within one generation.

6. One of the first reports of the secretary was devoted to the improvement of schoolhouses. It would be impossible to believe the accounts of the condition of the public schoolhouse in many communities of New England, sometimes even in the larger towns, were it not confirmed by the testimony of people who, like the author of this essay, have been the victims of the chronic neglect and indifference of the average American community of that date to the condition of the children in those old "temples of science." With a surprising wealth of information and the entire resources of his matchless eloquence, persuasion, and satire did the secretary assail this conspiracy against the children in the public schoolhouse. The result was that within two years of his appeal to the people $500,000, and during the twelve years of his administration $1,000,000, had been expended, not in expensive city temples, but in the construction or improvement of a great number of country and village school buildings. A course of Mr. Mann's illustrated lectures, with stereopticon views of the outside and inside of the old-time American school-

house, would be one of the most popular entertainments of the day. The fact that our American common-school teachers never had the European habit of living in houses provided by the State, indeed were largely drawn from the younger stratum of the population, and often, in the old time, "boarded round" in the families of the district or were cared for in some temporary place, may have told on the structure of the schoolhouse. The poverty of fit sanitary arrangements and the deficiencies, often the intolerable discomfort. of the average schoolroom of that period would be almost incredible to the children of the present city schools, who are often largely of foreign birth and from humble homes, but who guard their schoolhouse and grounds as carefully as if they were in a crystal palace. Would that Horace Mann could now revisit the scene of his labors and be led from one beautiful and convenient schoolhouse to another till he felt that coming back to his own dear Commonwealth and the country he loved so well was like a welcome to one of the "many mansions" reserved for the faithful in the life eternal.

7. We have already seen how young Horace Mann appreciated and used the little public library given by Dr. Benjamin Franklin to the Massachusetts town named from himself. It was the passion of his life to bring the opportunity of good reading to all the children and youth. In 1837 probably not one-sixth of the 600,000 in Massachusetts had access to a free library of any sort, for although perhaps no town was then destitute of a moderate collection of good books of the kind then most in vogue, either held by some association or lyceum or in the parson's "study," yet these were seldom free. Of the 180,000 volumes in the 229 social and 50 school-district libraries in the State in 1838, valued at $200,000, it is estimated that half were in Boston, which then had 62,000 people. Only 25,000 people had free access to the 15 town libraries of 3,000 to 4,000 volumes each, and to the district-school collections of 10,000 volumes, valued at less than $4,000. There were no general circulating libraries out of Boston, and only one-tenth of her population had access to those in the city. The immediate success of the district-school library in New York and the amount of money expended on it, $55,000 for several years in succession, had greatly interested Mr. Mann. He declared the passing the law of Massachusetts in 1837 for moderate State aid to this subject one of the most important educational measures since the original establishment of the common school. It may be that the disappointment from this venture was somewhat owing to the limited supply of readable children's literature, which has been largely the growth of the past fifty years. We remember the patient spirit in which we plodded through the dreary Sahara of Rollin's Ancient History and the "classic" essays and poems of the Queen Anne writers that filled the shelves of our minister's study, and the delight, as in the coming of a bright spring day, when the new doctor came to town and brought the first copy of Shakespeare and a hundred good novels and volumes of voyages and travels.

Mr. Mann's literary taste was pitched on a key too steep and severe for the comfort of his young friends who came to him for advice. Probably no collection of more "useful" and more unreadable books than the 50 volumes he caused to be written or edited for the original public-school libraries of Massachusetts were ever offered to the young people of any State. The subsequent movement for town and city libraries, often the gift of their old school boys and girls, filled with the most attractive works of the day and connected with a reading room for the leading journals and periodicals, had well-nigh extinguished the public-school library until its recent revival under the administration of Secretary Dickinson and State Librarian Tillinghast gave it a new lease of life. But, with all these drawbacks, the movement was a good one and out of it has come the present overwhelming opportunity for reading. Indeed, it may well be questioned whether the boys and girls of fifty years ago, who were compelled to "read, ponder, and

inwardly digest" the few good books available till they had become a vital part of their mental constitution, were not more profited by their reading than multitudes of our young folks who revel in a surfeit of the so-called literature supposed to be appropriate to the present needs of young America.

8. The experiment of compulsory attendance at school, if it was ever a reality in the early colonial period, had been wrecked against the American Declaration of Independence and the proclamation of "Liberty throughout the land to all the inhabitants thereof." Certainly, there was no attempt to enforce the practice when Horace Mann sat down hard in the official chair of the secretaryship that became a throne during his reign of twelve years over the educational mind and heart of the old Commonwealth. In 1836 the first attempt was made to deal with the scandal of child labor in the factory, which, like a black shadow of despair, always accompanies the coming in of manufacturing industry, and even to-day is the disgrace of half our own country. In 1850 the truant laws were first put in the statute books of Massachusetts. We read with amazement that, as late as 1842, it was lawful in Massachusetts to keep a child under 12 years of age at work in a factory ten hours a day. From this barbarism to the legislation of 1876, only one generation, by which no child under 10 years of age could be employed in any manufacturing establishment, or under 12 while the public schools are in session, or under 14 without having enjoyed twenty weeks of schooling in the year, was an upward step into a higher civilization. And nobody in America had labored and prayed and stormed and insisted more persistently to this end than Horace Mann.

9. The one hateful side of the old common school, even of the original college of the early time, was the severity of discipline. It was not especially a feature of the New England Puritan life, for in the South, where family discipline was never so rigid, the absolute brutality of corporal punishment in schools is remembered as a hideous dream by multitudes of people yet alive. Our own recollection in Massachusetts goes back to the time when no day passed in school without that chapter of "accidents" which it was assumed would "happen in the best of families." Parents and school authorities seem to have been in league with the schoolmaster and schoolmistress to hold the vagrant spirit of the rising generation under the terrors of the ferule and rod. There were plenty of teachers who apparently exhausted their small mental outfit in devising original and painful methods of torture for the idle, dull, and disobedient. To clutch a big book held at arm's length; to "hold down a knot" in the floor by one finger; to stand on one leg; to "sit with the girls;" to be thrashed, "jointly and severally," as it pleased the despot in charge; to isolate or mass the victims—all these horrors come back to us as a nightmare only rivaled by the awful ghost novels we read "on the sly" at night. In our own county, a district not backward in education, lived two pedagogic pugilists whose business during the winter months was to "keep out schools" that had rebelled against their teacher and often put him out-of-doors and "broken up the school." And this cheerful work produced such an exhibition of daily brutality as curdles one's blood to recall.

Against this barbarous style of discipline as a system Mr. Mann arrayed himself from the first. He abhorred corporal punishment in all its hateful variety, while reluctantly confessing that there is a possible limit at which patience and "moral suasion" may give place to the song of the birch. But he pleaded for the natural right of the child to happiness during his school years and the possibility of a nobler and more successful method of school government with all his heart.

His terrible scoring of the thirty-one Boston grammar-school masters for their chronic habit of punishment inaugurated a reform by which every teacher who inflicted corporal chastisement was compelled to make a record of it, with the reasons thereof, always open to public inspection. Of course, a great deal of the

disorder and disobedience in schools of every sort at that day was the result of the bodily discomfort, mental weariness, and moral exasperation caused by the old-time schoolhouse, incompetent teachers, and the stupid methods of instruction then in vogue. Mr. Mann writes that, until the age of 16, he was never asked in school for the meaning of a sentence in a reading lesson; indeed, "the inquiring mind" was not in favor with the average teacher of the day. With the coming in of the improved schoolhouse, more attractive text-books and apparatus, better teachers and natural methods of instruction, the old savage ideas of "school government and discipline" have broadened out to the entire field of moral and religious or character training, of which government and discipline are but the outward garment. Dr. Nott, of New York, and President Wayland, of New England, had already inaugurated the great reform in college discipline in the interest of common sense, common justice, and common humanity. This movement, at a later period, was carried to its splendid culmination by Horace Mann, as president of Antioch College, Ohio. There, in a community of 500 boys and girls, gathered in from the homes of the new West and Southwest, in a village without police, with gardens and fruit orchards on every hand, there was such a spirit of order and cheerful respect for the moral proprieties and courtesies as had never been known in student life before that day.

All these topics are discussed in his seven published lectures and twelve reports in a manner at once broad and minute, with a patient elaboration of the details of common-school keeping, a splendor of illustrative imagination, a fervor of patriotic eloquence, and a solemnity and pathos of moral and religious consecration which characterize his method of treating this subject and constitute an era in the literature of education. It is this style of dealing with education as related to every essential interest of man, individual and social, that gives to these volumes a permanent value. Whatever elaboration of pedagogic culture or recondite excursion into the realms of psychology or biology may characterize the present or future discussions of our great educators, the time will never come when a thorough acquaintance with the writings of Horace Mann will not be the most wholesome corrective of extreme views, recalling the experimenter and speculator from wrestling with the technicalities of the schoolroom to the vast, wide, and profound world outside, from which the child comes to the teacher and to which he must so soon return to put in practice what he has there acquired of wisdom or manhood.

It is said that soon after the beginning of the splendid work of Dr. Barnas Sears in the Southern States as agent of the Peabody education fund a large collection of Mr. Mann's addresses, pamphlets, and reports found at Antioch College, Ohio, after his death, was distributed through these States with the best results. Of the number of educational writers that can be counted on the fingers of one hand who have compelled the attention of the large majority of intelligent and patriotic people of this Republic, Horace Mann stands yet supreme. And this supremacy he owes to the fact that, above all professional and technical preparation for his great work, he was the first educational statesman of the land, and nobody so clearly and broadly as he has discerned the vital relation of the common school to our American Government and order of society. And no man has set forth these relations in a manner at once so instructive to the student in college and so uplifting and inspiring to the intelligent citizen of every portion of the country.

At the close of this record of the twelve years' service of Horace Mann as secretary of the Massachusetts board of education it will be profitable to sum up the visible results of his work in the inauguration of the educational revival in New England, which was felt to the remotest border of the last Territory organized by Congress. But in 1843, when half his term of office had expired and he was per-

suaded to take a six months' vacation with his wife, with hope of recruiting his shattered health and for a leisurely observation of European school life. these results had already been achieved. Besides the new legislative action already referred to, which provided for a thorough system of reporting and a yearly abstract of the conduct of affairs being placed before the people of Massachusetts; besides a lifting up of the minimum of the school term to six months, which probably affected half the smaller towns of the State; the fixing of a more reliable compensation for the school committees, and the insisting that these, the only supervisors of schools, should perform their duties as laid down in the statute; the establishment of three State normal schools; the gathering of teachers into county and State associations; the organization of a great system of educational lecturing by the most distinguished men of the Commonwealth; the publication of the Common School Journal and distribution of many thousands of published documents among the teachers and the people; the establishment of district school libraries in many of the towns; the stirring up of the primary teachers of Boston to efforts for self-improvement; and beyond all, the soul of all, the mighty awakening power of this apostle of the new education, so that no little hamlet in the remotest corner of the Commonwealth escaped attention, while more and more his reputation was becoming national, there was a gratifying increase in the pecuniary support of the schools and improvement in all things connected therewith.

The first abstract sent forth by the board of education in 1837 informed the people of the State that Massachusetts had a population of 691,222 and a property valuation for public taxation of $206,668,580 in 1830. There were then 2,918 common schools in the State. The number of children and youth between the ages of 4 and 16 were 177,053. Of these, 141,837 were under instruction, with an average attendance of 111,500. The schools were in session through an average of six months and twenty-five days; but this average was secured by the Boston habit of keeping school "the year round" and of the forty or fifty larger towns or cities, which maintained a session of seven, eight, or nine months. In fact, one-third of the children of school age were not at school and probably one-half of the towns in the Commonwealth did not hold their schools in session more than four or five months. One-sixth of the children of the State were in 854 private schools, which, outside the academies, were generally of a temporary character, with no responsible supervision. Indeed, their status was unknown and unknowable outside the limited circle of their patrons. There were 5,961 common-school teachers employed, of whom 2,370 were men and 3,591 women. The male teachers were often college or academical students, teaching during their winter vacations and, as a body, were greatly superior to the women, who seldom enjoyed advantages for education in any way comparable with their brothers. The men worked at an average salary of $25.44 and the women of $11.38 per month, including board, generally in the families of the district. The amount annually expended from taxation, fees, and subscriptions for the free schools was $513,529.19, less than $3 per capita for the children and youth of school age. There were 854 private schools and academies, many of the former being vacation schools of practically the same character as the public schools and taught by the same teachers, though with a tuition bill attached, with 27,266 pupils, which cost $328,026.75, more than half the school money expended by the State on one-sixth of the children.

But this was simply the outward showing of a state of affairs which looked more discouraging the more completely it was uncovered. The city of Boston, with a population of 80,000 and a valuation of $80,000,000, expended on the 7,000 children in public only one-half of the sum given to the 4,000 in private schools. The older cities along the seacoast followed this example, while those of the interior, like Worcester and Springfield, reversed the order of expenditure. The boys

were more numerous in the public schools than the girls; the latter still held more under private instruction. Only 14 of the 43 towns directed by law to establish a free high school were complying with the statute. Not one-third of the school committees in the State were living up to the demands of the law in regard to the examination of teachers, visiting of schools, or any real supervision of the work in the district schoolhouse. Not a teacher in the State was the graduate of a normal school, and probably the majority of them had no education beyond that gained in the rural country schools, with perhaps a term or two at a neighboring academy. The condition of great numbers of schoolhouses, according to Mr. Mann's first report, was a scandal on the civilization of the nineteenth century. The habit of the wealthy and educated class of sending their children to private and academical schools was fast letting down the common school to the rank of a poor man's refuge and accounted largely for the indifference even of the class dependent on them for all the education possible for their own children. The lack of any professional training of teachers by lectures, suitable reading, and instruction was complete. No wonder the secretary, out of the depths of his great heart, wrote: "Into what a state of feebleness and neglect our common-school system has fallen, and how deeply decay has eaten into its vitals! It is hoped that when the people learn into what a dilapidated condition the whole frame of this venerable institution has fallen, they will rouse themselves to some correspondent exertion to save it from irretrievable ruin."

That the people did respond at once in the most effectual way, by putting this plea into legislative enactment, is evident. By 1845–46 the secretary could report: "In earlier years our reports were principally occupied in exposing wants. A much larger portion is now occupied in indicating present improvements." In 1843, after six years of his administration, the people were expending $585,000 for 195,000, and in 1845–46, $620,000 for 203,000 pupils in public schools, with a relative ratio of expenditure for private and academical institutions. One by one the legislatures came up to their duty of establishing the free high school. Many of the most distinguished men of the State were serving on the school committees, and generally this important official body lived more nearly up to its duty as the only supervising power of the Commonwealth. The secretary declared: "In no country on earth could the progress of a free system of education be so well studied in all its varieties as in the State of Massachusetts." Its compact location of the motive power of government in the township organization enabled each community to move without restraint with a beneficent spirit of rivalry from town to town. The reports and abstracts of the secretary were largely read by all intelligent people. Mr. Mann read every word of the local reports of the 300 towns in preparing his own two general reports of 5,500 pages on his return from Europe. Meetings were held for the express purpose of listening to the reading of his interesting public documents. In many of the smaller towns associations of good people were formed to visit the schools and encourage the teachers and people.

Boston was waking out of its lethargy of self-complacency; the school committee came down with a sharp word concerning the condition of schoolhouses unworthy so wealthy and beautiful a city as Boston. In 1846 Massachusetts stood at the head of the States in the wages paid to teachers, $24.51 per month paid to men and $18.07 paid to women, exclusive of board. The secretary wrote: "For the last two generations, with exceptions comparatively few, all the eminent men of the State, whether men of letters, physicians, lawyers, clergymen, legislators, or judges, had taught school, more or less, during the early part of their lives." The waking up to the improvement of the moral and religious teaching of children was marked. In 1847 there was not a common school in Massachusetts where the Bible was not read, although the State had not yet made Bible reading in the schools obligatory by law. The secretary declared that "far more has been

spoken and printed, heard and read on education within the last twelve years than ever before, were it all put together, since the settlement of the colonies." In 1846 the Bay State was spending, all told, for the schools $1,000,000, $1,000,000 for its churches, and far more for charities, and had already $60,000,000 invested in railroads at home and beyond its own limits.

A great improvement was marked in the discipline of the schools by moral and humane methods rather than by physical force. The maxim of the secretary, "No low nature can perform the office of a higher in the common school," was heeded, and a greater care was shown in the selection of teachers. The secretary's statements read like prophecy: "By what spirit are our schools actuated?" "Do they cultivate the higher faculties of the child?" "The children of the people must be fitted for society as well as for themselves." "Of all neglected or forgotten duties, in all ages of the world, the spiritual duties of children are the most neglected." "The old way of clearing the land of refuse population by war, pestilence, and famine is outgrown. All will stay with us, and we must educate men or suffer by being with them." In 1845 the secretary declares that the inequality in distributing the State funds to the towns has been remedied, and in no year has his advice and assistance been so eagerly and widely sought as in the present time. In 1843 the people of the State seem to have been thoroughly awakened to the improvement of schoolhouses, and had expended for this purpose alone, since 1837, $1,000,000, with a steady gain of $100,000 a year for the general management of the schools.

In short, the people of Massachusetts were responding in their own moderate and reliable way to the three propositions laid down by their great secretary of education, which may well be copied and hung up in every public schoolhouse in the United States to-day:

1. "The successive generations of men, taken collectively, constitute a great Commonwealth."

2. "The property of the Commonwealth is pledged for the education of all its youth up to such a point as will save them from poverty and vice and prepare them for adequate performance of their social and civil duties."

3. "The successive holders of this property are trustees bound to the faithful execution of this trust by the most sacred obligations; and the embezzlement and pillage from children and descendants have not less of criminality and far more than the same offenses when perpetrated against contemporaries."

On May 1, 1843, Mr. Mann was married to Miss Mary Peabody, sister of Elizabeth Peabody, so well remembered by American kindergartners, and of Mrs. Nathaniel Hawthorne, wife of the celebrated novelist, herself a woman of fine qualities and unusual literary ability. His health was at one of its periodical crises. After six years of prodigious activity and corresponding anxiety it was decided by his friends that a release from the workshop could alone save his precious life. His proposal, at his own expense, to make a tour of six months in Europe, combining the pursuit of health with the observation of educational affairs abroad, was accepted. He left the editorship of the Common School Journal in the hands of Mr. George B. Emerson and departed on his first and only journey across the great water.

His physical condition would have been alarming in any man less accustomed to "coming off conqueror" in the fight with the last enemy than himself. He could not sleep. As Dr. Howe said: "His mind went on of itself." He was tormented to distraction by neuralgia and submitted to the removal of "a whole mouthful of teeth" in hope of relief. His wife writes: "He fought all his editorial battles over on his bed at night." He carried old Massachusetts and her children on his heart wherever he went. In thirteen days from leaving home he was visiting the schools, prisons, and charitable institutions of Great Britain.

Nowhere does the absolute preoccupation of his mind in the absorbing work of his life appear in a more startling way than during this period.

He was received with distinction in Great Britain, and saw more that was characteristic of the Empire than was common for a visitor outside of official life. But the Puritan in his nerves and blood rose up in obstinate protest against the terrible contrasts of life in the Old World. At Eaton Hall, near Chester, the grand seat of the Duke of Westminster, the first of the great English estates he visited, he was shocked at the sight of infirm old women doing the hard outdoor work of strong men. He writes: "I left the magnificent spectacle in a state of mind I can not now express." Thomas Carlyle seems to have been in one of his least bearish moods, for his visitor went away with real enjoyment of "the genuine, irresistible, boyish heartiness of his laugh." He noticed that the dog kennels on the estate of the Duke of Buccleugh "were much better built and had a far more comfortable air about them than half the cottages we have seen in England and Scotland." "The object that called up the deepest and tenderest associations seen since I left home was the lowly, humble cottage in which Jeannie Deans is said to have been born." He could not understand the admiration of the Scotch for their native heather. To him it was "brown and lifeless, and had not a particle of beauty to ally it to poetry. * * * It looks as if it were dead when it came up." At York Cathedral he writes: "To me the sight of one child educated to understand something of his Maker and of that Maker's works is a far more glorious spectacle than all the cathedrals which the art of man has ever reared." Yet he was profoundly impressed by the cathedral at Cologne, and visited it again and again while in that city.

At a great fancy ball at Almacks he blurts out: "Such dresses! Such caricatures of humanity were enough to make a man call the baboons and kangaroos his brethren rather than these." But he remarks that "about twenty ladies were beautifully and tastefully dressed. The money of the others apparently did not hold out, for their dresses rose but just above the waist. Among the men there was not a single good head." At the Tower of London he exclaims: "Three millions of jewels in the regalia, and more than three millions of destitute, almost starving, subjects!" At Stafford House, the London residence of the Duke of Sutherland, he writes: "All this is splendid beyond anything I ever saw. Were there no crime and no poverty in the world how one could enjoy this." If it were not for the necessity of caring for his health he "would far prefer to be closeted in narrow apartments, working for the children at home, to all the joy of beholding this magnificent display of Scottish lakes."

In this preoccupation of spirit he journeyed through Great Britain and portions of the Continent for six months. He was by no means insensible to the attractions of noble scenery, rare cultivation of the land, splendid architecture, music and art, and the amenities of cultivated society. But, when he turned his back, in 1837, on the brilliant career of his early manhood to consecrate himself to the children of the Commonwealth, like the great apostle he said in his heart, "This one thing I do." Henceforth his wearisome days and sleepless nights, for twenty years, were to be given to the mighty ministry of education, which, in his vocabulary, represented nothing less than the entire training of young America for American citizenship.

But small rest was found for his body during these six months, crowded with experience that ripened into the future administration of his great affairs. It is doubtful if the European visit of any American in later years has borne a more abundant and precious fruitage to the Republic than this summer rush of Horace Mann from city to city through Great Britain, Germany, Holland, Belgium, and France, in pursuit of all that could be gathered for "his 80,000 children at home." He found popular education in England less advanced than in any country visited. Despite a general educational charity fund of several millions of dollars,

1,500,000 English children were living in complete mental destitution. A bill was then before Parliament for the establishment of a national system of education, to be virtually under the control of the clergy of the Church of England; even the certificate of a clergyman being necessary to secure employment in a factory by a child. The most flagrant favoritism was shown in the distribution of this charity fund; for the searching investigations that came several years later into the condition of the secondary education in England had not yet uncovered the scandal of so many of these endowed schools. At Oxford he heard elaborate courses of lectures given by learned professors to empty benches; the chief study under tutorship being Latin and Greek. He was informed that nine-tenths of the children in England received all their schooling before the age of 9. There was no effective system of national instruction till a generation after this.

In Scotland he found a different condition of affairs. The parochial-school system had there been in operation almost two centuries, but only one-third of the children in Scotland were found in this class of schools, the remainder being attended to by private arrangements. He was astonished, but not edified, at the prodigious activity and energy of the Scottish school life. The teachers and pupils performed double the amount of work that seemed possible in the schools at home. The masters were generally college graduates and aimed at a thoroughness of instruction, especially in language, nowhere else attained. The national system of common schools in Ireland was then in the early years of its success. Three hundred thousand children were being taught in schools in which the rival church authorities agreed to unite on unsectarian moral and practical religious instruction during school hours, with arrangements for theological training outside, the use of schoolhouses for religious and political gatherings being forbidden. He was greatly interested in Archbishop Whately, the most prominent author of this arrangement, and regarded him as one of the ablest and most catholic men of the Kingdom. The Irish system of prisons was seen and studied with intense interest. Several of the great private school corporations and benevolent institutions for children attached to others met his approval. But, outside a few architectural displays in private school buildings, he did not see a common schoolhouse in his entire visit that compared with a second-rate house at home. The children uniformly sat with their feet dangling above the floor, on benches without backs or desks, and in Great Britain, outside a few exceptional places, with small provision for the illustration of studies. The normal schools were private enterprises, and largely restrained by the sectarian policy of their management.

In Germany he found another condition of affairs, as far as the administration, methods of instruction, and spirit of the school life were concerned. He visited Prussia, Saxony, Holland, Belgium, and several of the minor German States, taking Paris on his return. Here, for the first time, he saw the result of a wise and powerful public policy in the organization of a system of education that included every family and went on with the irresistible force and precision of one of the powers of nature. In Prussia the minister of education was a member of the royal council, with a position, emoluments, and honors similar to other high officials of State. A complete system of normal schools supplied the country with educated men teachers. A thorough inspection of the schools was all the time going on by competent supervisors. So complete was the effect of the compulsory system that the children seemed born to go to school. In Saxony he found the most to admire, the little kingdom having a constitution and Parliament, "a good bit of ham sandwiched between Prussia and Austria." All the German States were only in the beginning of constitutional government. Austria had not yet succeeded in providing for the education of the whole people, but Holland was even more advanced than the German States. Belgium had established a system of schools in 1830, and France was moving in the same direction.

In these Continental States alone he found what he went for. Horace Mann

was preeminently an educational statesman of the progressive American type. He did not go to Germany, like so many scholars since his day, to admire the administration of imperial government or fancy that the motive power of public education in the United States could be safely transferred from the whole people to an aristocracy of learned men. He had no great faith in a compulsory education of the German type, with a bayonet prodding the waistband of every indifferent or obstinate subject. In his famous seventh report, made after the return from his European visit, after an elaborate explanation of the many superiorities of the German school system, showing the most thorough appreciation of its numerous excellencies, he closes with a most powerful and philosophical analysis of the essential difference between American and Continental European society. He explains the fact that a system of schools in many ways so excellent, had not yet materially changed the despotic character of society in Prussia. The reasons he found in the fact that, in 1843, the peasantry of Prussia had not yet been half a century out of the bondage of a practical serfdom; in the contamination of society from the evil examples of the superior classes; in the fact that the mass of the children were withdrawn from school at so early an age, only the superior youth being encouraged to go on even to the secondary education; and specially that, after school, there was nothing to stimulate that ambition for rising in life which is so powerful in every class of American youth. The popular saying in Germany, "The school is good; the world is bad," had condensed all these conditions into one sentence.

He failed not to comprehend the method and spirit that dominated the educational system. The masses of the people should be made sufficiently intelligent, moral and religious, content with their lot, patriotic, and with a childlike reverence and affection for their rulers. The school life was to him by far the most hopeful spectacle in all these countries. The teachers seemed to him, by all odds, the finest body of men he met—the true fathers of the young, rather than pedagogues of the old-time sort. Many of the improved methods of instruction now in common use in all good American schools were there seen in full operation. He admired the success in introducing the little children to proper school life, the skillful way of teaching reading, numbers, geography, nature-knowledge, especially the writing, drawing, and music. The discipline was after his own heart. In Holland corporal punishment had been abolished, and during his entire visitations on the Continent he never saw a pupil undergoing punishment. A beautiful spirit of affectionate confidence, like the sunshine, pervaded the schoolroom. He never saw a teacher sitting or using a text-book. A great variety of methods of illustration, especially for primary pupils, were noted. The schoolhouses were observed. They were greatly inferior to the better sort at home. The convenience of the children was hardly thought of, ventilation almost unknown. "The Dutch and Germans have no noses." "Everyone sleeps, even in summer, under feather beds, and only the convicts in the prisons have blankets!"

For six months, twelve hours a day, did this indefatigable educator "in pursuit of health" traverse this wide area of country. He found his Scotch friend, George Combe, in Germany, also an invalid, and the two wooed health by endless talks into the nights, which were often spent in reading public documents concerning the institutions visited by day. In Germany Mr. Mann was known to the children as "the white-haired gentleman." He went into every open schoolhouse door and absorbed information as through the pores of the skin. He was not the first of American explorers in that field. Already had President Bache, of Girard College, Philadelphia, made a valuable report concerning the public, charitable, and penal institutions of the Continent. In 1830 Rev. Calvin Stowe had visited Europe, at the instance of the State of Ohio, and given an interesting and widely read account of all he saw. But Mr. Mann went with such an outfit of enthusiasm, experience, and faculty of trained observation as no previous visitor.

His lofty manhood rose story by story above the head of the average school man. He saw and appreciated all that was to be seen of improved administration and method. He was in perfect sympathy with the loving spirit that so distinguished the schools of Germany especially from those of Great Britain. His large experience and intense interest in the criminal code and the working of the charitable institutions for the deaf, dumb, and blind and youthful offenders, and the great moral movement which under the name "the temperance reformation" has so blessed American society, enabled him to measure the value of that side of European life. He found nothing in the care of the insane to surpass the asylum established during his early political life in Worcester, Mass. He gave close attention to the improved method of teaching the deaf, dumb, and blind as introduced in the asylums at Boston and Hartford. The prison discipline of the Continent still lingered in the barbarism of the dark ages. And above all, he overlooked the entire life of the countries he visited from the high vantage ground of educational statesmanship.

For these reasons this tour of six months, embarrassed as it was by actual feebleness of body and by the disability that he could only read and not easily speak the Continental languages, was one of the most important ever made since the years when Franklin, Adams, and Jefferson went abroad as the first representatives of the new American Republic. His seventh report to the board of education, made in 1844, was in many respects the most revolutionary and influential document ever launched on the tide of American public education. It was everywhere read, and everywhere awakened admiration and aspiration for a higher training of the teacher, better methods of instruction, and a more benevolent type of school discipline. It also woke up the last grand revolt against his administration. In 1845 Horace Mann, by universal assent, stood at the head of American education. Henceforth his life, as secretary of the Massachusetts board of education, Representative in Congress, a great schoolmaster let loose in the National Capitol, and president of Antioch College, Ohio, was a prolonged conflict with the "remainder of wrath" inherited from two centuries of crude educational experimenting still fondly cherished by a large body of men in all departments of American educational life.

From this important journey Mr. Mann returned to wrestle with new labors and confront an opposition which through his entire administration had been seeking occasion for an assault in force. On the publication of the famous seventh report, the most important document in behalf of the new education yet presented to the American people, it was evident that the protest against the new educational heresies must be made or their opponents "forever afterwards hold their peace." It came in the most impressive and respectable way, in the celebrated pamphlet issued by the thirty-one grammar-school masters of Boston. This document, written in a moderate spirit, was not so much a pronounced attack on the advanced views of the secretary, as illustrated by his observations in the schools of Germany and in Holland, as an elaborate denial by those gentlemen of what they declared his exaggerated statements concerning the condition of popular education in Massachusetts. Without positively assailing the reform movement, of which the board of education, through its secretary, was the representative, they made the curious mistake of regarding a great deal in his statement of facts concerning education abroad as a covert disparagement and impeachment of themselves.

This document brought from Mr. Mann a powerful reply, in which the truth of his representations concerning the general conditions of the common school in Massachusetts at the time of his election to his office was established by an overwhelming display of statistics. No man ever better understood the art of massing figures upon an important point than he. His fiery rhetoric and brilliant illustrative imagination lighted up the long vistas of his facts as by an illumination of

electrical lamps. The effect was similar to the spectacle of the first use of the electric search light which I witnessed on a Mississippi steamer, when every plantation, village, and hamlet was caught in its night undress and flashed out upon the spectator in its dishabille. It was not necessary that the secretary should assail the Boston schools or depreciate the work of their masters. It was only important that the whole field of the reformed common-school life of the day should be illuminated by a skillful arrangement of facts and an exact statement of the results of the new order where applied, leaving the people to their own decision.

It is not necessary to revive the memory of that last important demonstration against the revival of the common school of Massachusetts, or to attempt to fix the responsibility for the evils and defects that were exposed by the relentless criticism of the great secretary and others that came to his aid. The masters only did what any body of educated men can always be expected to do, practically intrusted with despotic power in educational affairs. While nominally chosen by annual election of the school committee, they really had a life lease of these important positions. Indeed, this body of schoolmasters was the only abiding power in the Boston schools. Through their great influence, the neglect of proper supervision, and the preoccupation of the leading classes in their own affairs they really elected the school committee, appointed the teachers, and generally directed the whole organized scheme of discipline and instruction. There was yet no city superintendent of schools in Boston. The grammar-school department was divided into reading and writing schools, meeting at different hours of the day and presided over by separate instructors. While the teachers of the elementary grades had shown a commendable interest in the work of the secretary and were moving in the right direction, this higher realm of the grammar schools, where the great majority of the children received their last schooling, was practically a close educational corporation. There were a few progressive and a small group of faithful and hard-working men among this number, and the policy of the attack on the secretary was not adopted until after much discussion and against the protest of the ablest men of the body. After the first round of controversy one of the leading masters retired from the field. The ablest of all, though among the foremost in his contention against the German methods of instruction, subsequently came round to an enthusiastic indorsement of the new education, became a progressive professor of didactics in Brown University, and, through a vigorous old age, was known as one of the most attractive lecturers and instructors on all subjects relating to the common school.

This controversy was protracted over more than two years, through a small library of pamphlets, and stirred up a brisk discussion of educational affairs through the press of the entire country. The result was a signal triumph for the reformed education in Boston and a complete indorsement of the policy of the State board of education. Four of the assailants among the masters lost their positions on demonstration of inefficiency. Several of the leading citizens of Boston, like Dr. J. G. Palfrey and Hon. George S. Hilliard, were placed on the city school committee. A committee of examination of the schools was appointed, with Dr. S. G. Howe, Judge Parsons, and Hon. Charles G. Loring as members. This, the first thorough investigation of the city schools, revealed such a spectacle of mechanical instruction, abuse of corporal punishment, and neglect of physical comfort and health in schoolhouses that the secretary could well afford to retire and leave the contest with the people. A city ordinance was passed compelling the registration of all cases of corporal punishment in a book open to public inspection. A grand shaking up of the dry bones of routine, a partial curtailment of the usurped power of the masters, and the beginning of a reorganization of the entire school system prepared the way for the establishment of a city superintendency of education a few years later.

A simultaneous assault on the secretary by a portion of the denominational religious press brought out from Mr. Mann, more plainly than ever, his strong convictions on the importance of moral and practical religious instruction and training in the schools. Under his earnest presentation of these ideas the entire body of common schools of the State were using the Bible, not for a sectarian purpose, but as the handbook of private and public morals. The secretary's ninth report to the board of education, in 1845, is one of the most cogent, thorough, and illuminating addresses on moral discipline and character training in public schools ever written, and should be kept in publication as a treatise of permanent value for teachers. He writes: "By what spirit are our schools characterized? Do they cultivate the higher faculties in the nature of the children?" "The children of the Republic must be fitted for society, as well as for themselves." "Of all neglected or forgotten duties in all ages of the world, the spiritual culture of children has been most neglected." "No low nature can perform the office of a high one in the schoolroom." "Try to vitalize the conscience of a child, instead of tying him up to a set of rules." "The true teacher will consider the train of feeling not less than the train of thought which is excited by the exercises of the schoolroom." No idea was more abhorrent to Horace Mann than the extreme "secular" theory of the common school, advocated by an influential body of educators and to some extent actually enforced during the past thirty years. His counsel had a great effect on fixing the present use of the Bible in the common schools of Massachusetts by compulsory law, with ample safeguards for the rights of conscience.

One of the points of attack by the thirty-one Boston schoolmasters was that Mr. Mann was not a professional teacher, but a theorist let loose upon a professional class which represented the wisdom of experience. The charge was disposed of by the fact that he had, from his youth, been a teacher in the common district schools, a tutor in Brown University, for many years an active member of a board of education, and always more deeply interested in educational studies than in any other line of investigation. As an all-around educator, Mr. Mann's primary qualifications for his great position were:

1. A genius for morality and practical religion in their application to common affairs and a profound knowledge of the life of New England, including civil life, as if, from his cradle, its every feature had been impressed on his memory by a spiritual photograph.

2. A culture much more extended than that of the ablest schoolmaster; as an eminent and successful member of the legal profession; distinguished in public life as a member and presiding officer in the legislature, including a wide acquaintance with all classes of the people and a powerful influence over the foremost men of the Commonwealth.

3. His long and careful study of the problems of penal, charitable, and reformatory institutions, especially for youthful offenders, had greatly enlarged his comprehension of the complex problems of popular education. And, over and above all, his twenty years and more of educational life were characterized by a consecration to the children's cause that, like a great flaming light-house in the center of his being, made his opinions, conduct, and entire manhood as transparent as the day.

In his eighth report, 1845, the secretary enlarges on topics hitherto discussed, although he writes: "Up to the present time these reports have been largely occupied in pointing out defects; at present in noting the march of improvement." He warmly praises the great work going on in New York, and declared that State was doing more than any in the world for common schools. He fails to notice that the leading educational spirits in that State had been men and women from New England. The original common-school legislation in New York was pushed through by a group of Connecticut born and bred members of the legislature,

the first State superintendent of schools, in 1820, being Gideon Hawley, of that State. Dr. Eliphalet Nott and Mrs. Emma Willard were the pioneers of the great reforms in the higher education of young men and women. The later movement that culminated in the results so highly estimated by Mr. Mann originated in western New York, where the New England element was an overpowering influence. Wadsworth, May, Hosmer, Dwight, and Page, and others too numerous to mention, were the leaders in the great revival contemporaneous with Mann. It is true that, in the outward arrangements of the common school the Empire State displayed that characteristic energy and skill of executive capacity in public affairs in which it was always foremost in the Republic. Its system of common-school supervision, local, county, and State, was well planned. Its legislatures were more generous than those of other States, and its teachers somewhat better paid. But there, as always in this and other directions, the prodigious power of local administration in which New England has always excelled, with less display of educational machinery, has secured better results in the actual schooling of the children.

The tenth report of the secretary was chiefly concerned with the educational history of the Commonwealth. It was a carefully prepared and admirably written document. It showed the gradual steps by which the State had advanced from the original law of 1647 in which the radical idea of universal education was shadowed forth until the establishment of the State board of education, almost two hundred years later. Like all the secretary's reports, each a laborious and exhaustive treatise on some aspect of public education, this should be taken out of its hiding place in the volume of his collected works, reprinted in a cheap pamphlet form and widely circulated. There is no writing on education to-day superior to volumes that were produced through these notable years of the great revival. Certainly in the power and elaboration with which the general idea of the American common school was presented, the breadth of view in the discussion of school government and administration, even in the treatment of improved methods of instruction, we shall find little to equal and less to surpass the works of Horace Mann. His pen seemed to move by a power without himself. For nine years he edited the Common School Journal and wrote a large portion of its contents. His correspondence was immense. His home became a sort of "intelligence office" in educational affairs, thirty letters a day being his common diet. He had achieved the foremost place in the admiration and reverence of the American educational public, as the chief administrative representative of the reformed common school, and was known abroad as no other educational leader in our country has been even until the present day.

In 1847, in his eleventh report, he returns to his favorite theme of the relation of the common school to public prosperity, and discusses this topic with his usual thoroughness, enthusiasm, and power of concentration. He says: "Far more has been spoken and printed, heard and read on this theme within the last twelve years than ever before, were it all put together, since the settlement of the colonies." "Spain has handled more gold and silver than all the other nations, but is now the poorest nation in Christendom." "Ignorance is fatal to prosperity." "Reading and writing are not education; the habit of publishing statistics of education predicated on reading and writing reveals the false idea of education." In 1847 there was not a common school in Massachusetts where the Bible was not read, although not required by law.

The time was now approaching when the great secretary could afford "to take account of stock" and estimate the outward results of his ten years of such labor as few men have given to the cause of education in any country. In his last report, 1848, he goes over again the wonderful record of popular education in the material development of the people. During the eleven years of his administration $1,000,000 had been expended in the building and repairing of schoolhouses,

more than the entire school property of the State was worth in 1837. A corresponding improvement in all the sanitary arrangements had been witnessed. Three State normal schools had been established—at Lexington, afterwards West Newton; Barre, afterwards Westfield; and Bridgewater—all under superior teachers and all sending forth a class of graduates who every year have done remarkable work, not only in Massachusetts, but all over the Union. The establishment of the teachers' institutes and gathering of teachers' associations inaugurated one of the most effective agencies for the uplift of the profession.

The Common School Journal was without question the ablest and most influential organ of the great revival, and its volumes to-day are a model of what a journal of education should be. He had waked up a powerful interest in popular education among the leading men of the State, all of whom, almost without exception, were ready by voice and pen to forward the enterprise. The school laws of the State had been revised, especially in the interest of a more effective administration by the school committees of the rural schools. The proper graded system was being established in all the large villages and cities. A great reform in school government and discipline had been inaugurated, especially in discarding the use of prizes and destructive emulation and the decline of corporal punishment. A decided advance had been made in primary education in the direction indicated by Mr. Mann in his report on the German schools. The old wasteful habit of a multiplicity of schoolbooks had given way to a uniform series of improved text-books. The movement for the establishment of school libraries had borne good fruit, perhaps the most reliable result being that out of this was developed the free town library, now almost universal through the State. The local appropriations for education had steadily increased with the larger attendance on school and greater length of school terms. Half the school population of Boston was already gathered from the new foreign immigration, and the problem of the church parochial against the common school was coming to the front.

But these general items of progress were but an index to the greatest work done in these notable twelve years. In that time the people's common school had been lifted from a questionable to an assured position of permanent superiority in the estimation of all classes of men. The administration of public education had become a subject of general public interest. Nowhere was there a trace of the apologetic tone in the spoken or written plea of the secretary, a mighty sermon eleven years long to all peoples in all portions of the domain. With a relentless severity sometimes bordering on exaggeration he exposes every defect of the present condition. But never does he waver in the assertion that all this is but the abuse of the system, due to popular indifference, professional incompetency, ecclesiastical bigotry, and the same causes that always and everywhere hinder the progress of God's kingdom on earth. We read somewhere of the palace of a great lord in England where during every hour of the day could be heard in every corner of the vast pile the music of an organ in the chapel. So through all these years of the official life of Horace Mann was the Commonwealth filled with the sound of his inspiring summons to the people to wake out of sleep and put forth the entire energy of the Commonwealth in behalf of the children. Full well did his prophetic soul contemplate the swift on-coming of the awful years of trial for the Republic. At the end of half a term in Congress he wrote: "You do not know how homesick and Statesick I am—that is, how I long to get back among the boys and girls of the Massachusetts schools." He writes Sam. J. May: "The schools will be found to be the way that God has chosen for the regeneration of the world. God is never in a hurry, but we are."

Mr. Mann had now served the State of Massachusetts eleven years as secretary of the board of education with a fidelity and consecration of ability rare in official life. His wife writes: "During all his educational life he had never allowed him-

self one day of pure recreation. If he made a visit to a friend, some educational errand was sure to lay in ambush or some plea to be entered for the furtherance of his cherished plans. He had not the art of lying fallow and thus gathering new strength for labor." She continues with a charming description of his life with the three children given to him in the providential marriage by which he obtained a home and doubtless added a dozen years to his already exhausted life. Always somewhat lacking in personal tact and the politician's art of "mixing;" even severe, stern, and almost ascetic in his social tastes: during the later years of his life a total abstainer from strong drink, tea, and coffee and a fierce hater of tobacco in any form; opposed to the recreation of dancing in the State normal schools; even uncertain about the reading of fairy tales and history by children, and never thoroughly appreciative of romance and poetry, he was always a dear lover of little children. As president of Antioch College he was probably the most approachable and thoroughly interested in every student of any great university magnate since Dr. Nott.

At the period now under consideration he was once more prostrated by the reckless habit of overwork in which he had indulged for the past eleven years. It is almost amusing, were it not so pathetic, to read his sage, positive ideas of the obligation of all men to adhere to the divine laws of physiology, as in his comment on the death of Dr. William E. Channing, while no public man in America more evidently brought himself to his grave at the very crisis of perhaps his greatest triumph than Horace Mann. But his example is only another illustration of the "higher law" of consecration to a great cause at all hazards, in obedience to which every movement for a larger life in society is advanced by the personal sacrifice of its leaders. Horace Mann was built physically for an athlete and centenarian. But he began life with fitting for college in six months, kept himself always a suffering invalid and a "light weight," though more than 6 feet high, and died at 62, because there was no more to be given.

But now came across his educational career an episode of return to the political life abandoned in 1837 to assume the office of secretary of the Massachusetts board of education. John Quincy Adams died, and from every side came up the demand that Horace Mann should consent to be elected as his successor in the House of Representatives in the Congress of the United States.

There was much to induce him to resume his political career. His preliminary work had been done as the leader of the great revival in common-school education. The reforms he had inaugurated were now well under way in the legislative body which alone had the power to carry on the work by the gradual method only possible to such progress. The terrible toil of a post in which he was both superior and subordinate in official work, the target of an opposition that as it passed over to a numerical minority lost nothing of its intensity and personal malignity; his growing interest in the antislavery cause, which after a generation of popular agitation had invaded the Government of the United States, never to let go its hold till the close of the civil war, fifteen years later; possibly an overestimate by himself and his friends of the probable influence of the chief educator of the nation tranferred to Congress; conspired to urge him to this change of life. His only chance for living seemed to be a change of work, although it might be to an even more absorbing and exhausting occupation.

He was elected, and early in the year 1848 took his seat in Congress. But the Massachusetts State board of education insisted on his retaining his office of secretary for a year to come. He soon found that "he had assumed new duties without being released from old ones." He writes from Washington that "he finds himself a sort of educational intelligence office at the national Capitol, at least thirty letters a day on topics of this sort alone to be considered and answered." He yielded to the importunity of Dr. S. G. Howe and Charles Sumner to take up the case of Captains Drayton and Sayers, on trial before a court in the District of

Columbia for abduction of negro slaves on vessels under their command. This alone absorbed a good part of his time during the first year of his residence at Washington. The demand on him as a lecturer on education, temperance, and the whole range of topics lying adjacent to his central idea could not be resisted. The result was that during the four years of his Congressional career he was one of the most laborious public men in the country.

But it can not be said that from the point of view of political statesmanship these four years in Congress were the most distinguished or useful portions of his public career. Endowed with some of the highest qualities of a great political agitator, possibly a successful statesman in a revolutionary period, he had been too long engrossed in his life work of educational reform to change his sphere of labor with impunity. As an educational statesman at a time requiring a singular union of courage, aggressive policy, and a moral enthusiasm verging on prophecy, no man in America has been so eminently successful. His criticisms and decisions indeed often brought him into sharp antagonism with his own reliable supporters and quite alienated the more "radical" fraternity, who discard "policy" in the attempt to enforce abstract truth at all hazards, though the heavens fall, wrecking the cause itself in the catastrophe. But he returned to political life at a time most inauspicious for the political reputation or even usefulness of the kind of man he was.

The tremendous controversy of the "compromise measures" of 1850–1852 was already on. The most celebrated statesmen of the period were shaken from their feet or swept out to sea by the incoming tide of civil war. Horace Mann could testify as eloquently as the most impassioned reformer against slavery, which he regarded as the one menace of the Union. But while this attitude made him the unflinching opponent of the opposition, he was compelled, by his constitutional conservatism in administration, to adhere to the party that sent him to Congress. By his support of the Hon. Robert C. Winthrop, of Massachusetts, for Speaker of the House of Representatives, and similar votes, he woke up an even more relentless hostility among people who through culture and position had been his coworkers in the educational revival at home. His opinion of the nonconforming sort in public affairs is well expressed in his words: "How strange is that hate of an evil thing which adopts the very means to secure its triumph! How strange that love of a good thing that destroys it."

But it is doubtful if Mr. Mann ever fully realized the essential difference between the position of an educator and a politician. The statesmanship of the one is not the statesmanship of the other. The fundamental office of the educator is to so develop the manhood and womanhood of children and youth through the discipline of the heart, the head, and the hand that the graduate from school shall of himself be capable of dealing with all questions of practical importance in private and public life. The central idea of republican government is that a perfectly educated people can be trusted to know their rights and meet public emergencies as they occur. The office of the statesman in politics is, with an unfaltering devotion to the eternal principles of freedom, justice, and humanity, to adjust his policy to the present aspect of public affairs and neglect no opportunity of gaining a point in behalf of the people, whatever else may be neglected. Herein is the notable superiority of the Anglo-Saxon peoples, which, during the involved and obscure battle for liberty which,

> "Bequeathed from bleeding sire to son,
> Though often lost is ever won,"

has been the author of all the progressive constitutional government now existing in the world.

American history has not yet come to a final estimate of the great patriotic statesmen of the era preceding our civil war. Certainly Mr. Mann had not the

outfit for impartial and successful political statesmanship at that critical period. In his seat in the House of Representatives at Washington, as in the office of the secretary of the board of education in Boston, he was still the great schoolmaster and educational statesman. Indeed, he was probably induced to go to Washington by the hope of establishing the national department of education which came twenty years later, and over which his friend and co-worker Henry Barnard was the first Commissioner. In his controversies with the opponents of educational reform in Massachusetts he had acquired a "short method" of dealing with a disputant, prodigiously effective under the circumstances, but quite out of place in a body like the national House of Representatives. Mr. Blaine, in his remarkable eulogy on President James A. Garfield, has set forth in striking words the mental constitution of this body and the prodigious difficulty of acquiring or exerting influence over it. Mr. Mann always appeared to the majority of its members as an eloquent and patronizing pedagogue, lecturing the Representatives of thirty-two "sovereign States" as an excitable and high-toned college president might harangue a crowd of uproarious students on the edge of a rebellion. Only once he seems to have obtained an almost universal attention by a remarkable speech on education. This address brought around him a crowd of admiring listeners and woke up a new interest in general education in many of the leading Southern Members of Congress. At the close of his first term of service he was reelected, although his attack on Daniel Webster, then at the summit of his personal popularity among the conservative classes of New England, had so estranged thousands of the most influential people of these States that he could henceforth hardly expect to live in peace at home. His call to the presidency of Antioch College, Ohio, in 1854 was a blessed reprieve from a position which would have been an endless conflict during the remainder of his active life.

But whatever may have been the influence of his great activity in the cause of liberty and union in Washington and through the country, he never doubted that his real place was at the helm of the revival in universal education. One of his most notable deliverances was a letter to Rev. D. Wright, jr., on the controversy concerning moral and religious instruction in common schools, especially as applied to the contention of the bishops of the Catholic Church. He says, "Moral qualifications, and ability to inculcate and enforce the Christian virtues, I consider to be even of greater moment than literary attainments in the teachers." He believes that such qualifications can be found among the disciples of all creeds and ecclesiastical organizations, and would only require in the teachers a wise and strict avoidance of the sectarian spirit and method. He writes: "I have always and under all circumstances held that the Bible is a book that should be introduced into our schools." His own fidelity to conscience is always to be noted. "I shall try to keep my conscience, though in so doing I may lose my office." He sees clearly that to go into politics from education is "going from the frying pan into the fire," and writes to Charles Sumner, not yet in the Senate, who is urging him on to some new effort: "I think you are rather the hardest taskmaster since Pharaoh, and I am not sure I ought to stop with that old Egyptian scamp."

To Father Pierce he writes: "I have not the slightest expectation of ever feeling any attachment for my present position. I have no idea that I can make any effective impression on the body with which I am associated. From present appearances I have not run away from correspondence on schools and education, but into it. I may have an opportunity to do an unseen work in this behalf—even greater than I have ever done before. I have seen enough already to give me even a deeper conviction of the necessity and indispensableness of education than I ever had before. It is the only way whereby a Republic can be saved."

Herein we can not doubt was this four years of political life a valuable education for Mr. Mann. It removed him from the portion of the country most favorable to educational reform to the real center of national public thought and

action and showed him, as he could well read the lesson, that it is only as a whole people is lifted up to a higher intelligence, virtue, and executive capacity that a crisis such as then confronted the American Republic can be peaceably and effectively dealt with. To his friend, Dr. Jarvis, he writes: "All the kind things you say point to what I would do, rather than to anything I have done; indeed, what I have done falls so far short of what should have been done, that I feel somewhat of an emotion of shame whenever the subject is called to my mind." His best work was now done through frequent opportunities to lecture, and among these efforts should be mentioned a splendid address before the Young Men's Mercantile Library Association, in Boston, November, 1849.

It is interesting to read his estimate of Henry Clay, then near the close of his splendid political career, though clothed in the obsolete phraseology of phrenology: "I have been studying his head. It is a head of very small dimensions. Benevolence is large; self-esteem and love of approbation are large. The intellect, for the size of the brain, is well developed. His benevolence prevents his self-esteem from being oppressive; and his intellect counteracts the action of his love of approbation, and saves him from an excessive vanity. His vanity, however, has at several periods of his life, led him into follies. He derives his whole strength from his temperament, which is supremely nervous, but with just as much of the sanguine as was possible to put into it. Considering the volume of the brain and the size of the head, it has the best adjusted faculties I have ever seen."

It is perhaps well for civilization that the average father and mother are not a pair of high-strung physiologists, even when a Horace Mann, can deliberately write such a sentence as this: "If men understood their duty, no man would have any more children than he could support, educate, and leave in an eligible condition behind him, any more than a prudent farmer would have more stock on his farm than he could support with profit to himself and with humanity to them. The launching of a human being into this world, with a moral certainty of his being unhappy and miserable, I regard a far greater crime, in the abstract, than sending a human being out of it." "In the abstract" something may be said of such a theory. But what family of industrious habits, good character, and fair intelligence in our country can predict what will be their ability a dozen years hence to educate and fairly bring up a family of children? And who can predict that any child, however and whenever born into the world, is destined to happiness or misery? Certainly, the conclusions of the extreme physiologist put into practice in the only way such a theory could be applied, by all sorts and conditions of people, would inflict on society a hardness of heart and a combination of personal misery and social demoralization compared with which the present errors in family life are not to be mentioned. The radical error, and it is a fatal error of much of our "practical" science and the pedagogy derived therefrom, is the notion that there is no Almighty love at the center of the universe that watches over the immortal life of the least child, and that the eternal destiny of anyone is wholly intrusted by Providence to any teacher, parent, or anybody.

In wide contrast to such extreme speculations we read words that touch a vital point in all teaching. "Can the pupil reproduce what you teach him? This is the all-important point in teaching. Has a lesson been so learned that the pupil can restate it in words or exemplify it in act, or draw it on the blackboard, etc." He ran against the theological animus at Albany, N. Y., where, after his own lecture had been delivered in the church of the famous Dr. Campbell, of whom President Andrew Jackson said, "Dr. Campbell and I can not live in Washington together," the church was closed against the whole course, including Theodore Parker, Drs. Orville Dewey and Andrew Peabody, and he writes, "Isn't this beautiful?" Indeed, for these political capital cities, of which Albany, N. Y., was then the most celebrated, he had little respect. After a long course of lectures in New York he writes: "I wish it were possible for some man or men to spread them-

selves over this great State and see that the children are as well taken care of as the pigs." Yet to the last he extols the Empire State as chief in the Union in its skill and zeal in organizing public education. He thinks the girls of western New York, as he saw them in their little coeducational colleges, the finest in the country. And he was doubtless greatly influenced by what he saw in the splendid country, western New York—a "revised and corrected edition" of New England—to cast in his lot with what was even at this late period "the west," Ohio. It gave him great pleasure to see that, after years of obstinate opposition and ridicule from many of the leading teachers of the deaf and dumb in our country, his ideas of instruction, put forth in his seventh report, were adopted and largely put in operation.

It was doubtless not only politically but controversially a mistake for Mr. Mann to carry his opposition to the policy of Daniel Webster to the extremity it assumed. But however elevated may have been his motives in this memorable controversy, its reaction was the practical close of his political life, and followed him like an ominous shadow to his grave. Although reelected to Congress in 1850, on the rising wave of opposition to the "compromise measures," then on the verge of enactment into law, Mr. Mann never seems thereafter to have felt at home in Washington. He had fallen upon the reaction that through the North preceded the final outbreak of hostility to the slave power, and counsels like his were not heeded at the capital. He now seems to have been oftener absent from Washington and more given to lecturing. These lectures, on temperance, education, and his favorite theme, loyalty to the divine laws of nature, were eagerly sought and were always instructive and powerful. He was greatly interested in the effort of Miss Dorothea L. Dix to move Congress to an appropriation of public lands for the education of the insane, and although this effort failed, she did succeed in obtaining aid for an institution in the District of Columbia.

In a brief letter to a young men's debating society in New York he enforces the golden rule of all true oratory and debate, that all should be for the furtherance of the truth. His coming to Washington in 1851, in his second term in Congress, with his family, was signalized by a publication of his antislavery speeches in a volume of 600 pages. This session of Congress was chiefly notable for political intrigue by the numerous candidates for the Presidency of the United States, which resulted in dropping all the prominent statesmen conspicuous in the late struggle and nominating Mr. Franklin Pierce, of New Hampshire, and Gen. Winfield Scott, of the Army of the United States, as rival candidates. Although in a measure favorable to General Scott, the candidate of the Whig party, the interest of Mr. Mann in political affairs from that date visibly declined. He was no longer in full sympathy with the party to which he had been accustomed to look for the most favorable policy in behalf of freedom, and the formation of the Republican party was yet six years away. He had been already approached in connection with the presidency of Antioch College, Ohio. His only venture as a maker of schoolbooks was at this period, in a laborious effort to prepare a series of arithmetical text-books on a new principle. The idea, as we get it, seems to have included or implied the present enlarged method of instruction in mathematics. His correspondence with Mr. Downer, of Boston, George Combe, and others on public affairs is so rich and illuminating that it is a matter of great regret that we have not larger extracts from it in the biography prepared by Mrs. Mann.

Especially is it little less than a calamity to education that his entire correspondence with Henry Barnard, the only American educator of that period to be compared in eminence with himself, should have been lost. We do find in a letter of introduction of Mr. Barnard to George Combe a whole-hearted tribute to the merits of his great colaborer. He writes: "If you will put double all the credit you have ever given to me and pass it over to Mr. Barnard's account, you would hardly do his extraordinary services more than justice. His mind is full of wisdom, and his life has been full of devotion to this subject." In February, 1852,

on a lecturing tour in eastern New York, he first met Rev. Austin Craig, then a young clergyman 28 years of age, with whom his whole after life was singularly connected, whom he loved as a younger brother, and finally became associated with in his work at Antioch College. As already mentioned, about this time, in a lecture tour through western New York, his attention seems first to have been seriously attracted to the subject of the coeducation of the sexes in college. In several of the higher academical institutions, then misnamed colleges, he found a state of affairs that profoundly impressed him and opened new vistas of usefulness. From this tour of twenty-five successive nights of public speaking and visitation by day he returned to Washington "in better health than when he left."

As early as May, 1852, his attention had been called to the projected establishment of a college by the religious body known as Christians at Yellow Springs, Ohio. In a letter to Rev. Eli Fay he writes: "No event of my life has ever caused me more deep and solemn anxiety than the applications to become the candidate for the presidency of your proposed college at Yellow Springs, Ohio. * * * Miss Catharine Beecher prays, if I want any more comfort in this life, that I will not try to build up a college at the West, and she says Prof. Calvin Stowe held up his hands in deprecation of the thought."

But the idea, from the first, had taken a deep lodgment in his heart. He regretted that he "could do no good at Washington." The return to educational work in Massachusetts, after his break with the formidable body of conservative influential people in Boston, was practically impossible. The prospect of success in any coming change in public affairs was not brilliant, although Charles Sumner had been elected to the Senate of the United States by a combination that had removed Robert C. Winthrop permanently from public life, to the great advantage of education by the splendid services of this most accomplished of New England statesmen through the closing thirty years of his life as president of the Peabody Education Fund. The West, for Ohio was still regarded a Western State, opened the most inviting sphere of activity commensurate with the ability, reputation, and aspirations of Mr. Mann. The death of Robert Rantoul, jr., his old associate in the board of education in Massachusetts, almost at his entrance on a distinguished public career as a Member of Congress, seems to have given the final direction to his wavering determination. From this moment his mind was more and more engrossed by the thought of the new life beckoning from beyond the Alleghanies. On April 15, 1852, the crisis came. Mr. Mann was nominated by the "Free Democracy" of Massachusetts for governor of the State. He received the offer of the presidency of Antioch College, Ohio, on the same day. He accepted the latter office without hesitation. This decision finished his political career. For the coming years of his life he was plunged heart and soul in his crowning work, which may well be styled the revival of the Western American college.

Horace Mann was in his fifty-seventh year when, on September 15, 1852, he was nominated for governor of Massachusetts on an independent political ticket, and on the same day accepted the invitation to the presidency of Antioch College, at Yellow Springs, Clark County, Ohio. With no abatement of zeal for the political opinions for which he had contended with all his might during the four years of his Congressional life, he had become fully convinced that the impending crisis in national affairs had not yet culminated and that as a candidate for governor of Massachusetts, doomed to certain defeat and beyond any other public man politically obnoxious to the solid conservatism of the State, led by the great Senator, Cabinet minister, and Presidential aspirant, Daniel Webster, his status as a politician would henceforth be located at zero. And, as if destined to emphasize his retreat from public life, about this time he had been drawn into perhaps the most exasperating and personal public controversy of his life, with Mr. Wendell Phillips, representing the extreme wing of the Garrisonian antislavery movement.

Evidently there was nothing to be done but to turn his eyes to some new phase of the educational revival in which he was still acknowledged by all competent judges to be the leader who represented most completely the position of American educational statesmanship.

That he accepted the offer of the presidency of what was then a new Western college with joy and found in its contemplation a new lease of life can not be doubted. The first meeting of the faculty, already elected by the trustees of the institution, with the exception of two of his own friends nominated by himself, at his residence in West Newton, Mass., was harmonious. He left the State early in September, 1853, "weeping like a child," as he turned his back forever on the Commonwealth to whose uplift he had consecrated the best years of his life and which later placed his statue, erected by the contributions of the school children of Massachusetts, on the capitol terrace opposite that of his old antagonist, Daniel Webster—fit representatives of the conservative political and progressive educational types of statesmanship by which the Bay State has risen to her present exalted position among the Commonwealths of modern times.

There was much to attract Mr. Mann to this new field of labor in the West. Antioch College was established by the religious denomination of Christians, then a numerous and growing body, especially in the region commanded by this its first institution of the higher learning. Yellow Springs, Clark County, Ohio, was then a rural hamlet, clustered about a well-known summer resort, in a beautiful and fertile quadrilateral, inclosed by the Ohio, the two Miamis, and the Mad river, 60 miles north of Cincinnati, between the present flourishing cities of Springfield and Xenia. It seemed almost an ideal situation for the college, which its new president beheld in vision as he set his face toward "the great West." The institution was situated almost in the center of the most densely populated portions of the three Western States—Ohio, Indiana, and Kentucky—and perhaps more central to the constituency he hoped to attract than any locality beyond the Alleghanies. Good living was very cheap, the climate genial, the natural conformation of the country attractive by its scientific interest to the geologist and the botanist, easily accessible to the city of Cincinnati, still, in 1853, the center of culture in the vast region beyond the mountains. The religious denomination that founded it was known as theologically the most progressive among the evangelical churches of the North and Southwest, with only the Bible as a creed, and an increasing section of its younger clergy and educated laity pledged to freedom of Scripture interpretation and a progressive policy in the higher education. It had been decided that the college should be coeducational and with no distinction of race, in these respects perhaps the only considerable foundation of the higher education in the West, save Oberlin, Ohio, which had taken that position. It had also "broken the record" as the first of the important Western denominational colleges that had elected a layman to the office of president. It had "struck twelve" by inviting the foremost common-school educator in America, despite his political entanglements, to what must necessarily be very largely the personal administration of a new experiment, and he had been permitted to bring several teachers of his own selection and to inaugurate his own method of college instruction and discipline.

The present system of free high schools was then hardly established in the West out of the cities, and the majority of the academies and colleges of all these States of the North and Southwest were strictly sectarian and generally in no respect of high reputation. The rising University of Michigan was the only State university in the Northwest that had attracted the attention of the educational East. Never before or since has there been a more interesting opportunity to establish a college of the higher grade of scholarship, free from the trammels and traditions that still bound the higher education of the original thirteen States in allegiance to the old British ideals. Only thirty years before, at the University

of Virginia, under the leadership of the venerable Thomas Jefferson, and thirty-five years later, in Tulane University, New Orleans, La., under the presidency of William Preston Johnston, has such a peculiar opportunity offered itself to an American educator.

All this Mr. Mann appreciated. His twelve years' service in the revival of the common school in New England had trained him in the advanced ideas and policy of the elementary, secondary, and normal school. His four years' service at Washington had made him thoroughly acquainted with the progressive and energetic spirit of the Northwest and its desire for a higher and broader type of college and university life than had hitherto prevailed. He was always unmindful of pecuniary reward, though always ridden by an almost fanatical sense of public and private pecuniary obligation. This was a serious personal disadvantage when his pecuniary interest conflicted with his sacred obligation to the good cause of the uplift of the coming American generation. He probably was not sufficiently informed of the fact that the obstacles to such an enterprise as that in which he was now embarked were necessarily greater in the new than in the older section of the Union. He went forth to the closing five years of his glorious career, which, despite all the disasters and discouraging features in the material affairs of Antioch, was perhaps as memorable in its relations to the system of the higher education in the West as his earlier and more public work to the common school in New England.

He found the progressive people of the West and Southwest ready to welcome him to the leadership in the revival of the higher education in the States tributary to Antioch. He was inaugurated as president in October, 1853. His inaugural address, of which Thomas Starr King wrote him from Boston, "There is vitality enough in your inaugural to make a college thrive in Sodom," was delivered to an enthusiastic open-air assembly of 3,000 people. Standing on the front steps of the main college building, the already venerable president received a gift of three Bibles for the use of the different departments, and in reply set forth in eloquent and significant words the idea of the founders of the institution, on which hinges the entire history of the higher Christian education in the Republic. The tables of the unfinished dining hall were cleared of the fragments of everyday use and spread anew with the examination papers of the 150 young people who applied for entrance, only 8 of whom were organized into a freshman class. His own scheme of administration, as concerned with the courses of study, discipline, and the general management of the educational and religious affairs of the institution were accepted. His original plan included a thorough department of pedagogics for the training of teachers, the preparatory classes being utilized as a general practice school. This arrangement would have placed Ohio at the head of the West in this great reform. More than 1,000 young people applied for admittance during the first year, representing all the Western and Southwestern States, with a strong contingent that had followed him from the Central States and New England. That there might be no bar to success on the religious side, Mr. Mann consented to the ceremony of baptism and became a member of the Christian denomination, thereby assuming the office of college preacher and professor of natural theology and philosophy.

But from the first the new college bore within itself the seeds of financial ruin. Like so many of the new schools of the Western and even the older Middle States at this period, it had been established on the financial "delusion and snare," a numerous body of holders of "scholarships," each of whom had a vote in the election of trustees. This small sum of a scholarship of $100 with an indefinite payment, and only the annual interest available for the support of the institution, was, of course, a foundation of sand, especially as each holder of a scholarship was entitled to send a student virtually free of tuition charges. A beautiful wheat field of 20 acres had been given for a college campus, and buildings had

been projected and partially erected on credit. The Christian denomination was comparatively poor and unaccustomed to a canvass for contributions to a seat of the higher learning. It was soon evident that from the West little financial aid could be expected, as each Christian body in that vast area was already overburdened with its own enterprises, and the uncertain financial condition reported by the administration failed to commend itself to the comparatively few people of wealth not already interested in sectarian foundations.

This is not the place to rehearse the melancholy financial history of Antioch College during the few years of the presidency of Horace Mann, notably the years when it stood up beyond the Alleghanies as an object lesson in the revival of the higher education. Suffice to say that, after herculean efforts, the president for more than a year receiving no salary, the impending failure came upon it in 1857. This crisis was "tided over" until 1859. At the commencement of that year a new corporation was formed, largely by the influence of distinguished Eastern friends, Rev. Henry W. Bellows, of New York; Dr. Edward Everett Hale, of Boston, and eminent laymen representing all portions of the Northern States, with timely and efficient support from the churches and people of the Unitarian faith in Boston, New York, Brooklyn, Chicago, and Cincinnati. A new board of trustees was chosen, undenominational in its character, though with a generous recognition of the original Christian constituency. Mr. Mann was reelected president, and, had his life been spared, the prodigious educational success of Antioch College would for the first time have enjoyed the solid foundation of a reliable financial establishment.

But the earthly service of a twenty years' leadership in the great educational revival of the Republic was finished for Horace Mann. He died, and with his departure his beloved institution gradually subsided into the position of hundreds of our new American educational enterprises, though Antioch has always retained the radical ideal of its founder. At present, after a varied history, it remains a respectable institution of learning, under the management of its original friends, chiefly attended by the youth of the Christian denomination in the South and West.

Neither is it profitable to recall the personal trials of President Mann and the painful embarrassments of his educational administration by the obstinate jealousies and the persistent opposition of adverse elements in the body of administration and instruction. All this is an old, old story in the history of numerous American colleges. But apart from the financial weakness, this would not permanently or seriously have interfered with the final success of Antioch. For Horace Mann was no tyro in the arts of public controversy or in the skillful manipulation of the varied elements of an administrative educational policy in the face of any or all forms of opposition. As it was, he carried his point in every conflict of this sort, weeded out of the field the incompetent and hostile members of the faculty, and splendidly vindicated his own theory of instruction and discipline. Had his life been spared he would have been, under the new management, in the full and almost unquestioned possession of an almost despotic control of the college.

As it was, Antioch College has sent forth, as teachers and promising students, one of the most reliable groups of young men and women ever graduated from an institution of learning beyond the Alleghanies. Four thousand students had passed through the college during the five years of President Mann's administration. At its first commencement a larger number of graduates appeared than in any of the schools that claimed the title of college in Ohio at a similar age, except Oberlin, in the northeastern portion of the State. And it is doubtful if any institution of learning west of the Alleghanies had, during this period, produced a greater number of promising graduates, especially teachers, than this child of the professional old age of Horace Mann. Even to-day, a generation from the death

of Horace Mann, the writer of these pages in his educational journeyings through the Southern and Western States, finds himself often in contact with eminent men and women in all professions who hail from the old Antioch hive. The college has sent from its body of professors and students college presidents to Harvard, Clark, and Wellesley, Massachusetts; an acting president to Cornell, in New York, and a president to the State University of Ohio, with numerous distinguished college professors, common-school superintendents, and eminent teachers in the higher seminaries of learning in many portions of the country.

The secret of the powerful and peculiar influence of Antioch College is found in the character and ideals of its first president, Horace Mann. The Northwest of forty years ago had not yet reached the undeniable superiority in the acceptance and development of the new education in the common school, and to a remarkable degree in the administration of several of its leading universities, which is now accorded to it by universal consent. Horace Mann went to Ohio as the best representative of the application of the superior new common-school American ideals to the higher education. He went as a layman, and to his last day was practically a lay educational statesman, standing on a college platform, the president of a coeducational college which offered even to the proscribed colored race the full opportunity of the higher student life. But to few of the leaders of education in these vast new Commonwealths was revealed the lofty and broad ideal of college life that he brought with him. Theodore Parker wrote to him: "I think Massachusetts had no seed in her granary which the West needed so much as yourself. Now God has sent you to Ohio, I look for a great harvest." That "seed" was the idea, never before so firmly held and wrought out with such invincible courage by the policy of the highest educational statesmanship—that the college and university are not a world by themselves, an educational realm set apart by a superior class insisting on a position that virtually leaves the people's common school a far-off, unrecognized region for the use of the "common herd." Antioch College was educationally reared, from corner stone to roof, on the broad foundations laid for the people's common school through the dozen years of the powerful and wise administration of Horace Mann as the first secretary of the Massachusetts board of education.

The spirit that flowed through it was free, broad, and catholic, thorough as the best of old Harvard, but expanded, adjustable, open to every race and both sexes, administered by men and women, with a transferal of all the improved methods of the common school to the conditions of a college in that portion of the country, already, from its magnificent demonstration of ability in affairs, indicated for leadership in the coming struggle for the salvation of the Union. Although the original plan for a great department of pedagogics was not realized, the entire seminary was perhaps the best general training school for teachers then set up in America. President Mann himself characterized it as "a college with the drill of West Point and the methods of the New England normal school." The result was the graduation of several hundred men and women who everywhere have "struck fire" as leaders in the professional and educational life through vast regions of the Republic, and the adoption of the educational spirit and methods associated with the career of Horace Mann by all the leading colleges and universities of the West.

But the most notable superiority of Antioch College was the triumphant success of the plan of self-government introduced by the president. From the old times when corporal punishment was administered at Harvard in the presence of the faculty arrayed in cap and gown by the president after a religious service, down through the reformed administrations of presidents Dwight of Yale, Nott of Union, and Wayland of Brown, there had been a steady growth of the idea that a college student is not necessarily an incarnate devil in ambush, on the watch for an opportunity for some novel display of mischief or wickedness, but an average boy,

the exception of Oberlin and Marietta, exceeded those of any other at the same age. More than 1,000 students have left us, and among them all scarcely one who has been with us long enough to imbibe the spirit of the place has left us a dogmatist or a bigot. There is a strong but a sober spirit of attention to religious interest among our students. The moral character and conduct correspond. On the east side of our grounds, and immediately adjoining them, is a farm of 400 acres, with gardens, vineyard, and orchards of trees, and on the northwest a large flower and fruit garden. On the southwest a Frenchman raises choice fruits for the market. Not one of these, for two years, has lost an apple, a peach, or a grape. Our dormitory, nearly filled with male students, has no teacher or proctor or overseer. In study hours it is as quiet as your house. We have no rowdyism, no drinking of intoxicating liquors, no gambling or card playing, and we have nearly succeeded in exorcising profanity and tobacco. All our faculty, except myself, are young (and I feel so), and are well qualified for their places and filled with a generous enthusiasm. Two of our professors are ladies."

The report of graduates now living confirms this remarkable statement, such as perhaps could not be made by any American college so large, under conditions in any way so peculiar. For an entire term Mr. Mann reports that there had been no occasion for the discipline of any student. Well might he write in 1858: "Our educational department has prospered beyond anything I have ever known or read of; the financial has been as disastrous as it could be. The college was bankrupt on the day it opened." After the failure of 1857 Mr. Mann himself had undertaken to manage its material as well as its educational, moral, and spiritual affairs. For two terrible years he labored and prayed and "endured all things" in the vain effort to save the corporation from its fate. When the end came, at the commencement season in June, 1859, and the whole corporate structure fell, the great father and educator who, for five years, had shone in the upper world above it "like a star from the East," blazed into his final transfiguration of the immortal life.

Of course, the peculiar success of the educational department of Antioch was the work of the president and the faculty gathered and inspired by him. Neither the West nor the East was then or is now capable of adopting in its college life a policy so catholic and a spirit at once so tolerant and severe, so effective as an education into the loftiest American manhood and womanhood. That Horace Mann shortened his life a dozen years by his five years' administration at Antioch College would go without the saying were it not possible that even this prodigious strain on all the vital force of his existence may, in itself, have been the elixir of life that kept him on his feet. He was to the last a great power in the land everywhere through his lecture career, and by his connection with the leading colleges in the country the best known educator, although he could not bring them to his idea that a student expelled after fair trial should be left by every institution as an outcast in the outer darkness of his disgrace. His one visit to St. Louis, Mo., resulted in the establishment of a State association of teachers, the transferal of his own ablest professor, Mr. Pennell, to the presidency of the St. Louis High School and afterwards of a celebrated girls' seminary connected with Washington University, and the founding of a city normal school, which has had as its distinguished presidents Dr. Richard Edwards, Miss Anna C. Brackett, and Dr. Louis Soldan. The acknowledgment of his power and influence was not wanting. He raised up such friends and enthusiastic supporters as Drs. Henry W. Bellows, Edward Everett Hale, and a host of the best men and women in the land; although his old political opponents in Massachusetts persistently refused to support his college by their money and put forth their best effort to verify the saying of Little Boston in Dr. Holmes's "Autocrat of the Breakfast Table," "No man ever left Boston that Boston could not spare."

Rev. H. C. Badger, for a time one of the faculty of Antioch College, writes: "The impetus with which the mind of Horace Mann smote our minds, rousing us and kindling a heat of enthusiasm, as it were, by the very power of that spiritual percussion—it was in this that he was so incomparable." Professor Christy says: "To my own mind, I am wont to symbolize the life of Mr. Mann by the figure of an ardent and strong youth begirt with the perils and temptations of life, with these four sentences engraved around him in characters of flame: 'What is the moral law of the universe?' 'What do I know or can know of it, and what does it teach?' 'That the moral law ought to be obeyed; that the moral law can be obeyed.' 'That moral law I will obey, ruat cœlum.' Morality as he saw it included what other men call religion. For five years he went out and in among us—our teacher and adviser, our reproof and encouragement—our father. He came upon our educational world like a star out of the east." A Cincinnati trustee reports that in a walk with the president through the glen at Yellow Springs they had lost their way and fallen into a slough with apparently neither beginning nor end. Mr. Mann called out from the advance, "Horace Mann never backs out;" and waded onward to dry land. Governor Salmon P. Chase declared: "There has never been anything like Antioch College in Ohio." Dr. E. S. Gannett, colleague and successor of Dr. William Ellery Channing, after a visit to the college, wrote: "In all the particulars that effect a moral and accountable being there never has been anything to compare with it on this earth."

But the end of these twenty years of concentrated work, done in as great peril to life as a soldier in battle, was approaching. He had fought the good fight and kept the faith. It was the great privilege of the writer of these pages to be present at the last commencement of Antioch College presided over by Horace Mann. He was evidently worn almost unto death through all the crowded days of that week. There was sickness among his children. The reorganization of the college was a work causing great anxiety, as the position of the president was involved. The final commencement day was a continuous strain of twelve hours until the end of the night reception at the president's house. I can never forget the spectacle of Mr. Mann standing at his high desk reading his final address to the audience that crowded the spacious chapel almost to suffocation. As he stood there, dressed with the exquisite neatness and elegance of "a gentleman of the old school," the setting sun almost shone through his wasted frame and lingered like a glowing halo about his head. One passage, which I do not find in the printed address, doubtless the inspiration of the moment, almost a premonition of his own approaching departure, on the immortality of the soul, moved me as I have been moved by no other argument or eloquence on that exalted theme.

But the day passed, and the crowd dispersed, with the exception of the few students and teachers detained in the village. The weather was torrid, with no rain for a month. The president fell into an alarming condition of exhaustion and restlessness. He could not eat or sleep, and only could drink the water brought from a distant spring by a relay of students. He shrunk from all noise except "the humming of little George." The physicians at last united in council with a distinguished medical expert from Cincinnati. As he came into the room, Mr. Mann, physiological and phrenological to the end, cried: "Stop, sir. Let me look at you." After a deliberate survey, he said: "I like your head and your body. Tell me what you can do for me." After a brief survey, the doctor left the room and told Mrs. Mann that her husband was already dying and could not live beyond twelve hours. With a thoughtful self-control, Mrs. Mann replied: "Let him sleep if he can to-night, and to-morrow he shall know."

In the morning he was told that his end was near. He lifted himself in his bed and said: "If that is true, I have work to do." He called his wife and children to his bedside, saying to each of his boys: "When you do not know what to do, ask

yourselves what Jesus Christ would do in your place." To all the faculty of the college present he gave his parting message concerning "my beautiful plans for Antioch." Then all doors were thrown open for two hours, and every student and everybody who would come was admitted. To each student some word of hope, warning, or inspiration was briefly spoken. To one who had been a great trouble to him and still was a doubtful case, he said: "What will you do with that splendid head of yours? Consecrate it. Let me consecrate it." And he laid his hands upon his brow in a final blessing.

To his beloved "Timothy," young Eli Fay, he said: "Preach God's laws; preach them; preach them. Oh, God, may you preach them until the light drives out the darkness." Of Professor Carey, now president of the Unitarian Theological Seminary at Meadville, Pa., he said: "Dear Carey—solid, steadfast, well-beloved, always wise, always right, always firm—tell him how much I loved him. Good, reliable, firm, gentle, beautiful Mr. Carey. And those good young men who have always done their duty, how I love them! Tell them how I love them. No words can explain how I love them." When asked if he were not exhausting himself, he replied: "No; it rests me." He said to Mr. Fay: "I should like to have you make a short prayer—low, peaceful, grateful."

Death came at last, not with bodily peace, but, as he had lived, through hours of labor, struggle, and delirium. The strong brain found it hard to die. At last God mercifully gave him rest; but death is not the word for such a translation.

CHAPTER XVI.

HENRY BARNARD.

By Rev. A. D. Mayo.

Foremost among the educational leaders during the great revival of the common school in the United States which ushered in the second half century of its existence under the national life, by common consent, must be ranked Horace Mann, of Massachusetts. This notable movement of educational revival and reconstruction began in the State which first established the people's common school, in the early colonial period, and had most thoroughly sustained it during the first half century of the national existence. And while the State of New York did somewhat anticipate this great movement in the establishment, in 1820, of a State superintendency of common schools, with some features of improved local organization, the subsidizing of academies for the instruction of teachers, and the formation of school libraries, yet the establishment of the Massachusetts board of education and the appointment of Horace Mann as its secretary placed the State of Massachusetts at the head of the reform which lifted the district school of the old time to the modern graded school, planted the two first State normal seminaries, set on foot the good work for the general improvement of schoolhouses, introduced superior methods of instruction, and, above all, secured the exaltation of the people's common school to its present condition as the central and most potent factor in the American system of universal education. Through twelve memorable years Horace Mann stood before the country beyond all others representing that educational statesmanship which is perhaps the most original and powerful feature of the American common school. It has seemed well to set forth in detail the remarkable work of this great educator, not only in justice to his own services, but as an object lesson of what is, in its aim, spirit, and method of operation even to-day the most imperative need of the common school through half the Union.

But it is important to understand that another work than that of Horace Mann was essential to the complete inauguration of this memorable era in American education which, perhaps more than any other influence, is responsible for the best elements of our present national civilization. Up to the year 1830 the American common school had been in a state of transition from the old-time British and Continental ideas to its own peculiar status as a vital product of the new American life. It may in a certain sense be said that the original district school of New England was suggested by the system of parochial schools for the people already established in Scotland and in some of the nations of the Continent of Europe. The New England grammar school was, as far as method of organization and instruction went, almost a copy of the private, corporate, and church grammar schools in England where the foremost of the leading colonial fathers had been educated.

The one radical difference, however, between the New England common school and its European predecessors was that, in all essential respects, it was a people's

influenced by what he saw during his short visit to Europe, although hindered in his investigations by the lack of a speaking knowledge of the Continental languages. Still, no man so correctly as he, at any time, has set forth the radical differences between the European and American idea and executive management of all classes of schools, a difference so often ignored by numbers of scholarly observers since his day.

The time was ripe in our country for the appearance of a great national representative of the literary side of popular education. There was an imperative need of a man of large native capacity, broad culture, and catholic temperament, competent to gather into his capacious mind the entire condition of educational affairs in all civilized lands; a man by birth, education, and social connections commended to the educated class of the whole country, yet of a patriotism so intelligent and intense that he should be found ready to cast in his lot as a day laborer, and, if need be, a martyr in the supreme cause of the uplifting of the masses in this Republic. He should be one who could set before every class of earnest and active teachers and educational workers the best results of educational thought and activity through Christendom in a form that would strongly commend itself to the foremost minds at home and abroad.

Such a man was Henry Barnard, of Connecticut, the great colaborer and complement of Horace Mann. It was fitting that the two American colonies which had first established the people's common school, and held fast to it through the entire colonial period, should give to the country these two great men, representing the segments of the complete circle of the national education: the encyclopedic literary genius that set before the public a complete picture of the world's best educational teaching and doing, and the educational statesmanship that planted in the conservative soil of New England the reconstructed common school which has been adopted as the most precious heritage of that section to the building of the new Republic.

Henry Barnard was born in Hartford, Conn., January 24, 1811, in the home of his ancestors, still the home of his old age. At the time of this writing, 1898, his age is 87. From his entrance into Yale College at the age of 16, his life has been a period of almost incredible activity. During its first half century it was largely engrossed in educational superintendence and the supervision of institutions of learning of all grades. But as the years have gone on he has been more occupied in the prodigious labor of building up the great storehouse of educational material, which has been declared by the highest European authorities the most extensive and reliable literary contribution to general education ever made by one man. While it may not be claimed that his labors as an educational administrator have surpassed those of others, they have yet been of great importance.

But the especial claim of Henry Barnard to national renown has been the direction of his mind to the crowning work of his life—the editorship and often authorship of the great American Encyclopedia of Education, the 50 volumes of the American Journal of Education. While still, in some ways, the most reliable authority for what has been done in departments of educational activity abroad, the peculiar merit of this vast work is found in the keen and practical sense displayed by its compiler in the special manifestations of educational life from the earliest years in our own country. Nowhere else can be found such a number and variety of interesting monographs respecting the growth of the educational spirit and organization in the different States of the Union. While diverted from his early determination to write the history of education in our country, Mr. Barnard's collection of material is itself the most complete picture of the educational life of a nation in literature. And now, through the preparation of an analytical index published by the Bureau of Education, this great

occasionally difficult of management, but accessible to the persuasive power of an administration of reasonable authority tempered with fatherly affection, aiming at the manly self-culture which is the basis of the highest American citizenship. It was reserved for Horace Mann, as the most notable achievement of a life crowded with victories over venerable delusions in education, to inaugurate and carry to a complete success a college discipline which was neither more nor less than gathering several hundred young men and women from the portions of the country least accustomed to parental and school control, including many who came with exaggerated and eccentric notions, not only of young men's and women's "rights," but of college freedom as "the right to do what anybody pleases," and teaching them how to become men and women fit to control the destinies of such a country as this Union was on the way to become.

Mr. Mann's favorite idea of the mischievous influence of school government by emulation was the soul of his method. He said: "Emulation makes bright scholars, but rascally men of affairs." Almost every morning, at the opening religious service of the college, he placed before the assembled students some new and often startling illustration of the highest ideal of an education founded on a sacred regard for the eternal laws of God, with such eloquence and fitness of appeal, such terrible sarcasm over sin and folly, with such splendid encouragement, aid, and comfort for every good resolution and reputable effort as was well nigh irresistible.

He gathered the members of his lower class about him in his own home, and by long and patient argument and entreaty persuaded them to agree to a combined effort at self-government, truthfulness, and obedience to law without the machinery of college spies and proctors and the wearisome conflict of wits between student and professor that discipline in so many colleges had become. His most difficult undertaking was the effort to change the regulation college idea of "honor" between students to the belief that their first duty and obligation was to the institution of which they were members. This obligation of honor should prevail in any matter that threatened the reputation of the college, whatever might become of the inclination of the students to stand by one another in the concealment of offenses against its law. Relentless and threatening as the judgment day against persistent wrongdoing and malignant opposition, he forbore with an almost divine patience with the crude manners, half-digested notions, and foolish and disobedient conduct of the weaker members of his little commonwealth.

Stern and resolute, sometimes brusque and even discourteous to his equals and opponents, he was always the confiding father of every student. He brought to Antioch many of the greatest men of the country as lecturers and visitors, and always gave to every student the opportunity of a personal meeting and hand clasp with the distinguished guests. But none of these men could sway, inspire, and draw all hearts after him by any spell of eloquence like himself. Many a boy sent to him as a final experiment in his education was won over to the right, and even those he was compelled to send away were often reformed by their last humiliation, and came to revere his memory. He seemed to live in the innermost life of every youth intrusted to his care. And so mightily did he prevail, that not only was Antioch, despite the perpetual malign influence of its enemies, some of them on the ground, perhaps the most enthusiastic and loyal body of students in the Union, but in the suppression of the ordinary vices of student life it has never been equaled and, until to-day, never surpassed. With none of the ordinary devices of penal government, he succeeded in making his student community probably the most orderly, courteous, and agreeable collection of 500 young people in Ohio or any State.

He writes to Samuel J. May in 1858: "At our first commencement we graduated more than the average number of the foremost eleven colleges in Ohio, and, with

the exception of Oberlin and Marietta, exceeded those of any other at the same age. More than 1,000 students have left us, and among them all scarcely one who has been with us long enough to imbibe the spirit of the place has left us a dogmatist or a bigot. There is a strong but a sober spirit of attention to religious interest among our students. The moral character and conduct correspond. On the east side of our grounds, and immediately adjoining them, is a farm of 400 acres, with gardens, vineyard, and orchards of trees, and on the northwest a large flower and fruit garden. On the southwest a Frenchman raises choice fruits for the market. Not one of these, for two years, has lost an apple, a peach, or a grape. Our dormitory, nearly filled with male students, has no teacher or proctor or overseer. In study hours it is as quiet as your house. We have no rowdyism, no drinking of intoxicating liquors, no gambling or card playing, and we have nearly succeeded in exorcising profanity and tobacco. All our faculty, except myself, are young (and I feel so), and are well qualified for their places and filled with a generous enthusiasm. Two of our professors are ladies."

The report of graduates now living confirms this remarkable statement, such as perhaps could not be made by any American college so large, under conditions in any way so peculiar. For an entire term Mr. Mann reports that there had been no occasion for the discipline of any student. Well might he write in 1858: "Our educational department has prospered beyond anything I have ever known or read of; the financial has been as disastrous as it could be. The college was bankrupt on the day it opened." After the failure of 1857 Mr. Mann himself had undertaken to manage its material as well as its educational, moral, and spiritual affairs. For two terrible years he labored and prayed and "endured all things" in the vain effort to save the corporation from its fate. When the end came, at the commencement season in June, 1859, and the whole corporate structure fell, the great father and educator who, for five years, had shone in the upper world above it "like a star from the East," blazed into his final transfiguration of the immortal life.

Of course, the peculiar success of the educational department of Antioch was the work of the president and the faculty gathered and inspired by him. Neither the West nor the East was then or is now capable of adopting in its college life a policy so catholic and a spirit at once so tolerant and severe, so effective as an education into the loftiest American manhood and womanhood. That Horace Mann shortened his life a dozen years by his five years' administration at Antioch College would go without the saying were it not possible that even this prodigious strain on all the vital force of his existence may, in itself, have been the elixir of life that kept him on his feet. He was to the last a great power in the land everywhere through his lecture career, and by his connection with the leading colleges in the country the best known educator, although he could not bring them to his idea that a student expelled after fair trial should be left by every institution as an outcast in the outer darkness of his disgrace. His one visit to St. Louis, Mo., resulted in the establishment of a State association of teachers, the transferal of his own ablest professor, Mr. Pennell, to the presidency of the St. Louis High School and afterwards of a celebrated girls' seminary connected with Washington University, and the founding of a city normal school, which has had as its distinguished presidents Dr. Richard Edwards, Miss Anna C. Brackett, and Dr. Louis Soldan. The acknowledgment of his power and influence was not wanting. He raised up such friends and enthusiastic supporters as Drs. Henry W. Bellows, Edward Everett Hale, and a host of the best men and women in the land; although his old political opponents in Massachusetts persistently refused to support his college by their money and put forth their best effort to verify the saying of Little Boston in Dr. Holmes's "Autocrat of the Breakfast Table," "No man ever left Boston that Boston could not spare."

Rev. H. C. Badger, for a time one of the faculty of Antioch College, writes: "The impetus with which the mind of Horace Mann smote our minds, rousing us and kindling a heat of enthusiasm, as it were, by the very power of that spiritual percussion—it was in this that he was so incomparable." Professor Christy says: "To my own mind, I am wont to symbolize the life of Mr. Mann by the figure of an ardent and strong youth begirt with the perils and temptations of life, with these four sentences engraved around him in characters of flame: 'What is the moral law of the universe?' 'What do I know or can know of it, and what does it teach?' 'That the moral law ought to be obeyed; that the moral law can be obeyed.' 'That moral law I will obey, ruat cœlum.' Morality as he saw it included what other men call religion. For five years he went out and in among us—our teacher and adviser, our reproof and encouragement—our father. He came upon our educational world like a star out of the east." A Cincinnati trustee reports that in a walk with the president through the glen at Yellow Springs they had lost their way and fallen into a slough with apparently neither beginning nor end. Mr. Mann called out from the advance, "Horace Mann never backs out;" and waded onward to dry land. Governor Salmon P. Chase declared: "There has never been anything like Antioch College in Ohio." Dr. E. S. Gannett, colleague and successor of Dr. William Ellery Channing, after a visit to the college, wrote: "In all the particulars that effect a moral and accountable being there never has been anything to compare with it on this earth."

But the end of these twenty years of concentrated work, done in as great peril to life as a soldier in battle, was approaching. He had fought the good fight and kept the faith. It was the great privilege of the writer of these pages to be present at the last commencement of Antioch College presided over by Horace Mann. He was evidently worn almost unto death through all the crowded days of that week. There was sickness among his children. The reorganization of the college was a work causing great anxiety, as the position of the president was involved. The final commencement day was a continuous strain of twelve hours until the end of the night reception at the president's house. I can never forget the spectacle of Mr. Mann standing at his high desk reading his final address to the audience that crowded the spacious chapel almost to suffocation. As he stood there, dressed with the exquisite neatness and elegance of "a gentleman of the old school," the setting sun almost shone through his wasted frame and lingered like a glowing halo about his head. One passage, which I do not find in the printed address, doubtless the inspiration of the moment, almost a premonition of his own approaching departure, on the immortality of the soul, moved me as I have been moved by no other argument or eloquence on that exalted theme.

But the day passed, and the crowd dispersed, with the exception of the few students and teachers detained in the village. The weather was torrid, with no rain for a month. The president fell into an alarming condition of exhaustion and restlessness. He could not eat or sleep, and only could drink the water brought from a distant spring by a relay of students. He shrunk from all noise except "the humming of little George." The physicians at last united in council with a distinguished medical expert from Cincinnati. As he came into the room, Mr. Mann, physiological and phrenological to the end, cried: "Stop, sir. Let me look at you." After a deliberate survey, he said: "I like your head and your body. Tell me what you can do for me." After a brief survey, the doctor left the room and told Mrs. Mann that her husband was already dying and could not live beyond twelve hours. With a thoughtful self-control, Mrs. Mann replied: "Let him sleep if he can to-night, and to-morrow he shall know."

In the morning he was told that his end was near. He lifted himself in his bed and said: "If that is true, I have work to do." He called his wife and children to his bedside, saying to each of his boys: "When you do not know what to do, ask

yourselves what Jesus Christ would do in your place." To all the faculty of the college present he gave his parting message concerning "my beautiful plans for Antioch." Then all doors were thrown open for two hours, and every student and everybody who would come was admitted. To each student some word of hope, warning, or inspiration was briefly spoken. To one who had been a great trouble to him and still was a doubtful case, he said: "What will you do with that splendid head of yours? Consecrate it. Let me consecrate it." And he laid his hands upon his brow in a final blessing.

To his beloved "Timothy," young Eli Fay, he said: "Preach God's laws; preach them; preach them. Oh, God, may you preach them until the light drives out the darkness." Of Professor Carey, now president of the Unitarian Theological Seminary at Meadville, Pa., he said: "Dear Carey—solid, steadfast, well-beloved, always wise, always right, always firm—tell him how much I loved him. Good, reliable, firm, gentle, beautiful Mr. Carey. And those good young men who have always done their duty, how I love them! Tell them how I love them. No words can explain how I love them." When asked if he were not exhausting himself, he replied: "No; it rests me." He said to Mr. Fay: "I should like to have you make a short prayer—low, peaceful, grateful."

Death came at last, not with bodily peace, but, as he had lived, through hours of labor, struggle, and delirium. The strong brain found it hard to die. At last God mercifully gave him rest; but death is not the word for such a translation.

CHAPTER XVI.

HENRY BARNARD.

By Rev. A. D. Mayo.

Foremost among the educational leaders during the great revival of the common school in the United States which ushered in the second half century of its existence under the national life, by common consent, must be ranked Horace Mann, of Massachusetts. This notable movement of educational revival and reconstruction began in the State which first established the people's common school, in the early colonial period, and had most thoroughly sustained it during the first half century of the national existence. And while the State of New York did somewhat anticipate this great movement in the establishment, in 1820, of a State superintendency of common schools, with some features of improved local organization, the subsidizing of academies for the instruction of teachers, and the formation of school libraries, yet the establishment of the Massachusetts board of education and the appointment of Horace Mann as its secretary placed the State of Massachusetts at the head of the reform which lifted the district school of the old time to the modern graded school, planted the two first State normal seminaries, set on foot the good work for the general improvement of schoolhouses, introduced superior methods of instruction, and, above all, secured the exaltation of the people's common school to its present condition as the central and most potent factor in the American system of universal education. Through twelve memorable years Horace Mann stood before the country beyond all others representing that educational statesmanship which is perhaps the most original and powerful feature of the American common school. It has seemed well to set forth in detail the remarkable work of this great educator, not only in justice to his own services, but as an object lesson of what is, in its aim, spirit, and method of operation even to-day the most imperative need of the common school through half the Union.

But it is important to understand that another work than that of Horace Mann was essential to the complete inauguration of this memorable era in American education which, perhaps more than any other influence, is responsible for the best elements of our present national civilization. Up to the year 1830 the American common school had been in a state of transition from the old-time British and Continental ideas to its own peculiar status as a vital product of the new American life. It may in a certain sense be said that the original district school of New England was suggested by the system of parochial schools for the people already established in Scotland and in some of the nations of the Continent of Europe. The New England grammar school was, as far as method of organization and instruction went, almost a copy of the private, corporate, and church grammar schools in England where the foremost of the leading colonial fathers had been educated.

The one radical difference, however, between the New England common school and its European predecessors was that, in all essential respects, it was a people's

seminary, established, supported, supervised, and above all filled with the spirit of the responsible body of the New England people which from the first created the school, church, and state in this corner of the New World. But in process of time the common school of New England and of the North had drifted far away from its old European models. In every Northern State it had been modified by the prevailing opinions and imperative necessities of the time. There was, however, a very imperfect knowledge of what was being done among the different States that had adopted this method of popular education; and outside a few rather feeble attempts, no real cooperation was obtained between its foremost teachers and officials.

Meanwhile a great movement for popular education had come up on the continent of Europe. Led by Prussia and other German States, it had made its way to France and invaded the neighboring kingdoms of Holland, Denmark, and Sweden. A vast literature had sprung up around the works of Rosseau, Pestalozzi, and the group of voluminous educational writers waked into life by their radical theories. And although England has not been prominent as a leader in every progressive movement for the fit schooling of the whole people, yet in the British Islands, notably in Scotland and Ireland, a remarkable educational literature had arisen.

It was of the first importance that now, when the American people were becoming thoroughly aroused to the necessity of a complete reorganization of their entire system of universal education, they should know what had been accomplished and what was being widely discussed elsewhere. While everything in state, church, and society that comes to us from abroad must undergo a thorough examination and adaptation to the peculiar needs of our republican civilization, it is only a perversion and caricature of patriotism that resists the acceptance of the best thought and life of all peoples for the enlargement and enrichment of our own. This Republic has a claim to all that is good and true which has been achieved by the entire experience of mankind. And in no department of the national life is this experience more valuable than in the realm of popular education, which is the soul of a people's order of society.

Even before the period now under consideration, more than is generally understood, the improved methods of school organization and instruction had been introduced into the country. Thomas Jefferson and Joseph Cabell, of Virginia, had brought from their residence abroad a considerable acquaintance with the university life of the Continent, and Cabell had visited the schools of Pestalozzi. Rousseau was no stranger to an increasing circle of readers, for whom the radical literature that preceded the French Revolution had great attractions.

As early as 1817, Judge Archibald D. Murphy, of North Carolina, had presented to the legislature of that State an elaborate system of popular instruction, the fruit of his studies and observations in the United States and Europe. Many of the presidents and professors, especially of the Southern colleges and academies, were from Great Britain, and occasionally from the Continent. The Moravian brethren of Pennsylvania had introduced the educational ideas of their great bishop, Comenius, in their own denominational schools. Joseph Lancaster had worked and died in the United States. Neff had established schools in Pennsylvania and the West according to the improved system of Pestalozzi. Mrs. Emma Willard had traveled abroad, and brought home advanced methods for the higher education of girls. Before the general court of Massachusetts had moved, the legislature of Ohio had authorized Prof. Calvin Stowe to make observations in Germany, and his account of what he saw there had been published and republished in this and several other States. Professor Bache, in the interest of Girard College, Philadelphia, had made one of the most reliable reports of the method of training orphans, and the improved elementary and secondary school methods in Great Britain and on the Continent. Horace Mann was himself greatly interested and powerfully

influenced by what he saw during his short visit to Europe, although hindered in his investigations by the lack of a speaking knowledge of the Continental languages. Still, no man so correctly as he, at any time, has set forth the radical differences between the European and American idea and executive management of all classes of schools, a difference so often ignored by numbers of scholarly observers since his day.

The time was ripe in our country for the appearance of a great national representative of the literary side of popular education. There was an imperative need of a man of large native capacity, broad culture, and catholic temperament, competent to gather into his capacious mind the entire condition of educational affairs in all civilized lands; a man by birth, education, and social connections commended to the educated class of the whole country, yet of a patriotism so intelligent and intense that he should be found ready to cast in his lot as a day laborer, and, if need be, a martyr in the supreme cause of the uplifting of the masses in this Republic. He should be one who could set before every class of earnest and active teachers and educational workers the best results of educational thought and activity through Christendom in a form that would strongly commend itself to the foremost minds at home and abroad.

Such a man was Henry Barnard, of Connecticut, the great colaborer and complement of Horace Mann. It was fitting that the two American colonies which had first established the people's common school, and held fast to it through the entire colonial period, should give to the country these two great men, representing the segments of the complete circle of the national education: the encyclopedic literary genius that set before the public a complete picture of the world's best educational teaching and doing, and the educational statesmanship that planted in the conservative soil of New England the reconstructed common school which has been adopted as the most precious heritage of that section to the building of the new Republic.

Henry Barnard was born in Hartford, Conn., January 24, 1811, in the home of his ancestors, still the home of his old age. At the time of this writing, 1898, his age is 87. From his entrance into Yale College at the age of 16, his life has been a period of almost incredible activity. During its first half century it was largely engrossed in educational superintendence and the supervision of institutions of learning of all grades. But as the years have gone on he has been more occupied in the prodigious labor of building up the great storehouse of educational material, which has been declared by the highest European authorities the most extensive and reliable literary contribution to general education ever made by one man. While it may not be claimed that his labors as an educational administrator have surpassed those of others, they have yet been of great importance.

But the especial claim of Henry Barnard to national renown has been the direction of his mind to the crowning work of his life—the editorship and often authorship of the great American Encyclopedia of Education, the 50 volumes of the American Journal of Education. While still, in some ways, the most reliable authority for what has been done in departments of educational activity abroad, the peculiar merit of this vast work is found in the keen and practical sense displayed by its compiler in the special manifestations of educational life from the earliest years in our own country. Nowhere else can be found such a number and variety of interesting monographs respecting the growth of the educational spirit and organization in the different States of the Union. While diverted from his early determination to write the history of education in our country, Mr. Barnard's collection of material is itself the most complete picture of the educational life of a nation in literature. And now, through the preparation of an analytical index published by the Bureau of Education, this great

measures which changed the entire character of the common school of his own State and set the copy for a work of revival and reconstruction in popular education which is even to-day only in its transition to what it may become. As a legislator his interest was at once attracted to the subjects of prison reform; the management of the asylum for the deaf, dumb, and blind, under the direction of Rev. T. H. Gallaudet; the rehabilitation of the Connecticut Historical Society, with the similar institutions grouped around the central interest of education.

In a previous review of the history of the common school in Connecticut we have told the story of the decline of popular education during the long generation following the establishment of the Government of the United States. Up to 1798 the common school of this State appears to have been the most effective in the country. The original colonial system of dependence on the town for the establishment, supervision, and partial support of the schools adopted and persisted in by Massachusetts had been eminently successful in Connecticut. But about this time the State established the first considerable school fund in the new Union—$1,000,000—which thirty years later was increased by the addition of the United States deposit fund and good management to $2,000,000. Its annual income of more than $100,000 gave $1.25 to each child of school age. But in connection with this admirable foundation, the State made a new departure which proved one of the most disastrous experiments ever tried in the history of American education.

This was the transferal of the entire management of the common school from the town to the "school society." The "school society" was, in fact, only the Congregational Church, practically made the sole local authority in educational affairs. It consisted of all the members of a parish or religious "society," was not limited by town lines, and was entirely separated from ordinary town affairs as acted upon in town meeting. The school society had the power to receive the portion of the income of the general State school fund annually distributed, at first on the basis of the taxable valuation, but after 1823 according to the number of children of school age within its limits. It administered the schools by the action of all legal voters in special meetings called for that purpose. It was empowered to elect a board of visitors, who were authorized to examine candidates for teaching and to approve the election of teachers by the district authorities. It could impose a tax for building schoolhouses and could locate them. It could divide its domain into school districts, which were empowered to elect the local trustees, who selected teachers, subject to the approval of the society, and gradually assumed the general management of the schools. The board of visitors was required by law to visit and supervise all the schools in their own society, to fix the courses of study, and select the schoolbooks. The society was also authorized to establish a secondary or high school, when required, and to report to the State authorities concerning the status of education, the proper expenditure of funds, etc.

Here would seem to have been, on paper, a scheme amply sufficient to insure successful school-keeping, especially when backed by the annual distribution of more than $100,000 to a school population of some 80,000, with power to tax for schoolhouses, a local right of taxation and a practice of assessing a pecuniary school deficit on the patrons of the schools. But the fatal error of the scheme was the switching off the common school from a great public interest, to be dealt with like other matters of high public concern by the people in open town meeting, upon a sidetrack, where it was managed as an interest apart by peculiar methods.

Just how this peculiar system of public school affairs, known as the "school society," was manipulated, in the practical administration of popular education during the long generation between this new departure and the opening period of educational revival, 1830–1840, is still a question among authorities equally uncer-

ish colony to an American Commonwealth, when the introduction of manufactures and the consequent growth of large villages and cities made the sum of $1.25 per capita a year a miserable pittance even for the old-time rural district school, to say nothing of the free secondary education. Another point is evident—that the clerical and cultivated classes during these years were at odds with the public school, and gave their influence and money largely to the building up of a rival system of private and denominational education. Whether this class actually discredited the common school through its own administration, or "sulked in its tent" and left the "common folk" to manage affairs without experience in educational administration according to their own narrow ideas of public economy, is the point in dispute. But there is no dispute that between the church and the State stools the people's common school fell to the ground and lay there until, aroused by the shout of the great revival from 1830 to 1860 under the leadership of Henry Barnard and a group of admirable coworkers, it literally staggered upward to the improved condition in which it was found at the breaking out of the civil war.

In 1837 an investigation by a legislative committee showed that not one-half of the children and youth of school age, 4 to 16, were in regular attendance on the common schools, and that the schools themselves were in a condition satisfactory to nobody. Of the 1,200 schoolhouses, only 300 were pronounced suitable, and more than half practically unfit for occupation. Large numbers of them were in an almost incredible condition in sanitary arrangements, often an outrage to common decency. There was no regularity of school attendance; no real examination of teachers; a general neglect of all legal requirements for supervision, visiting schools, or arranging courses of study. Two hundred varieties of schoolbooks made "confusion worse confounded." The 1,200 teachers were a "dissolving view" of men in winter and women in summer, the men receiving $15 and the women $6 to $8 per month, besides very cheap board; the large majority of them "boarding round" in the families of the district to save the board bills. Not one-fourth of the teachers in any term continued beyond the year in charge of the same schools. There was no pretense of any attempt for the professional instruction of teachers, apart from such meager general education as they could gain in the common schools and an occasional term at the academy. Not a dozen common schools in the State were furnished with libraries and school apparatus. Not a district or society in the open country, where nine-tenths of the children were schooled, imposed a tax for supplementing the State fund, and not one made an annual report to the State. The duty of the commissioner of the State school fund seems to have been confined to sending to each school society its proper quota, of whose use there was little report. Indeed, there was no general knowledge, either public or private, of the condition of public education. The school society meetings for the choice of officers and transaction of business were sparingly attended and often acted without a quorum. The superior people of the community, more and more shirked the office of school visitor.

The whole situation was summed up in the repeated complaints of a general public apathy concerning the common school. The people who used it, or did not care to school their children anywhere, appeared to be satisfied, and supposed Connecticut, educationally, was still at the head of the country. It was almost impossible for the legislative committees to obtain information, the school societies often refusing to report their own inefficiency. In short, from the foremost in colonial days Connecticut had fallen nearly to the rear among the States that had in good faith established the common school.

Meanwhile the people of wealth, social influence, and superior education were more and more estranged from this apology for a common-school system. Every community of a hundred people had a private school. Yale College was still among the half dozen leading colleges of the land, under the direction of eminent

And the man was already there in young Henry Barnard. By common consent the flower of the best culture of his State and time, to whom all men were looking, he added to his numerous talents and accomplishments that spirit of consecration which is the one essential characteristic of the genuine reformer. He had already put on record the inspiring declaration, "So far back as I have any recollection, the cause of true education—of the complete education of every human being without regard to the accidents of birth or fortune—seemed most worthy of the consecration of all my powers, and, if need be, of any sacrifice of time, money, and labor which I might be called upon to make in its behalf." At the close of his remarkable speech, which, without further debate, carried the legislature almost as a unit in the support of the school law of 1838, he said, "Here, in America, at last no man can live for himself alone. Individual happiness is here bound up with the greatest good of the greatest number. Every man must at once make himself as good and as influential as he can and help, at the same time, to make everybody about him and all whom he can reach better and happier. The common school should no longer be regarded as common because it is cheap, inferior, and attended only by the poor and those who are indifferent to the education of the children, but common as the light and the air, because its blessings are open to all and enjoyed by all. That day will come. For me, I mean to enjoy the satisfaction of the labor, let who will enter into the harvest."

It is easy to be seen that the problem set for the young educational reformer of Connecticut was essentially different from that which confronted Horace Mann in Massachusetts a year before. For the common school of Massachusetts, although under a cloud of neglect, had never been derailed from the "through track" of direct public control. Every town and city had complete oversight of its own system of public instruction. It is true that the direct influence of the town and city had been greatly weakened by the extreme subdivision of these communities into school districts and the growing habit of leaving too much power in the hands of the prudential committee of the local school. But the town still elected a school committee, which was responsible for the general welfare of the schools and the examination of teachers; and, above all, the habit of direct local taxation for the free education of all had been established and never lost. Besides, the leading minds and the clergy in Massachusetts were more in sympathy with the common school than in Connecticut. It was easy for Secretary Mann to summon a group of men, distinguished in national affairs, to the hearty public support of his plans. Governor Edward Everett and Daniel Webster, Dr. William E. Channing, Dr. George Putnam and Rev. Caleb Stetson, John Quincy Adams, Governor George N. Briggs, and Robert Rantoul, jr., with the host of men of all professions highest in the esteem of the Commonwealth, cheerfully responded to the call to attend conventions, speak and write, and in all possible ways stand up for reform in the common school.

There was also a group of educational men, teachers and laymen like George B Emerson, Carter, Brooks, Sam. J. May, Cyrus Pierce, and President Humphreys, connected with academical schools and colleges, who cooperated heartily with the great educational statesman, toiling sixteen hours a day in the little Tremont street office of the secretary of the board of education. The chief work to be done was to wake up the masses of intelligent people, nowhere so eager to listen and ready to respond to the call to "go up higher" as in the Old Bay State, and through the cooperation of a friendly legislature to drive the chariot of educational reform with a free hand. And there was then, as now, in Boston and other cities of the State a body of generous-minded people of wealth ready to back any wise effort in behalf of philanthropy, education, or religion.

But the radical difficulty in Connecticut was that, for a long generation, the educational train had been switched off from the direct track of a public interest dealt with in the forum of the town meeting to the side track of a "school society."

Under these circumstances it was not strange that while Henry Barnard did find a strong support and high appreciation from many of the leading men of the State, like Governor Ellesworth, Dr. Horace Bushnell, and, later, Noah Porter, afterwards president of Yale College, yet the educated and superior class was not prepared to look with favor on his radical plans for the complete reconstruction of popular education. The stolid apathy among the masses of the people who still relied on the common school for their own children was not at once to be broken by the appeals and efforts of a scholarly, catholic, amiable young official, hitherto known only as a promising college graduate fresh from his foreign travels and ambitious of distinction as a public-school reformer. Indeed, it would have then been a hopeless undertaking to attempt to break up the school society, the radical weakness of the system. Dr. Barnard did not attempt this and, through the four years of his first term as secretary of the State board of school commissioners, seems to have studiously avoided that, the central point of attack.

His work was to visit the people in as many of the 140 towns as was possible; to inspect the schools; to become acquainted with the influential friends of popular education; to make numerous addresses; to awaken the attention of school visitors and teachers by a veritable shower of elaborate circulars of inquiry and suggestion, in themselves a valuable treatise on the new education; to write the series of educational reports that are still among the most reliable literature of the common school, and in the new Connecticut School Journal to begin the vast work of the gathering and publication of material for the teachers, the educational public, and the historian which we find complete in his great educational library, the American Journal of Education.

In general terms it may be said that the most reliable results of his administration were, first, the unmasking of the situation by the waking up of the latent hostility against the common school to an open declaration of war. This manifestation came to a head in 1842 in the report of a legislative committee which led to a reversal of the policy of 1838. This action first opened the eyes of the educated, influential, and patriotic people of the old State to the peril of their Commonwealth. Second, from this awakening there came up a genuine "common-school public," which, although not prepared to follow Mr. Barnard's suggestion on retiring from office of combining in a "Connecticut institute of instruction," did, at last, find itself, and eight years later recalled the defeated secretary and placed him again at the head of a system of public schools which has gradually outgrown its old defects and to-day is among the most effective in the Republic.

From the first there appears in Mr. Barnard a strong disinclination to occupy the public positions of great administrative responsibilities into which he was repeatedly thrust, though always somewhat under protest. He favored the appointment of Rev. T. H. Gallaudet, then at the head of the institution in Connecticut for the education of the deaf, dumb, and blind, as secretary of the State board of commissioners, believing him the most competent educator in the country. He even proposed to contribute money and influence to raise a fit salary for the office. Failing in this, he only consented to occupy the post of secretary for six months, without salary, and twice before 1842 urged his own resignation upon the unwilling board. His service during this entire term of office was pecuniarily as well as spiritually "a labor of love." He contributed to the cause as much as he received from the State. Indeed, he finally impoverished himself by his persistent contributions of money to the cause of education, largely by the publication of his great journal; never a popular magazine, for the same reason that an elaborate encyclopedia can not be made a popular periodical.

But the fact that his first appearance as one of the youngest members of the general assembly in 1837 and the manner in which he swept the entire legislature to the passage of the reformed school law of 1838, which, under the modest title "An act to provide for the better supervision of common schools," was in reality

"the commencement of a new era in the history of popular education of Connecticut," proves that there was a widespread sentiment against this policy of educational neglect and that a great expectation was awakened by the appearance of the fit man to lead in the policy of reform. The law passed the legislature almost unanimously after the one speech in the house of representatives by its author. From that remarkable speech can be gathered the entire programme of educational reform inaugurated by the great revival whose history we now rehearse. Dr. Barnard did not hesitate to lay his finger on the most sensitive spot in the controversy when he made "a forcible presentation of the needs of superior teaching, showing how the colleges and seminaries had made no preparation for it."

The law as passed, like the previous statute in Massachusetts, established a State board of "commissioners of common schools," consisting of the governor, the commissioner of the State school fund, and eight gentlemen representing the eight counties of the State. It is significant that President Wilbur Fisk, of the Wesleyan University, was one of the commissioners, while Yale does not seem to have been thus recognized. In Governor Ellesworth and Hon. Seth P. Beers, commissioner of the State school fund, the new secretary especially found a wise and persistent support.

The law provided that the duties of the board of school commissioners should be: (1) To ascertain the actual condition of the common schools of the State; (2) to keep the legislature informed of their condition by abstracts and reports, and to suggest plans for the improved organization and administration of popular education; (3) to visit the different counties of the State, through its secretary address the people, inspect the schools, and generally stir up the teachers, visitors, and other officials; (4) to edit a journal of education devoted especially to the cause of the common school.

The whole duty of the board may be summed up in the comprehensive title: A ministry of education in behalf of the people's common school, under the direction of the State. Like the Massachusetts State board of education, it had of itself no authority to do anything decisive in the change of existing affairs. But in New England this type of commission is always the most powerful lever for the uplift of any good public institution, as proved by the experience of the past sixty years. The way for the passage of the law had been prepared by such a partial report of the status of the common schools as could be obtained from an investigation by the committee of the legislature in 1837. Dr. Barnard, before the assembling of the legislature, had addressed a printed circular to every member of the general assembly, calling attention to the revelations of this report and urging prompt action.

The first act of Dr. Barnard after the organization of the State board was the publication of an elaborate address to the people of the State, the work of the secretary himself. With the true New England official habit, he hastens to disabuse the public mind of the idea that the board has any disposition or power to exercise authority upon anybody. It is simply a convenient arrangement to inform the people of the actual condition of their school affairs. "No inquiry of this sort has, as yet, been thoroughly and satisfactorily made. There has been no effective instrumentality for making it. The investigations, at numerous times attempted, have been very incomplete." Dr. Barnard goes on with admirable tact to appeal to the hereditary pride of the State in its educational affairs, to pay a well-deserved tribute to its fame in colonial days, and to suggest that, of late, while many Commonwealths and nations at home and abroad are waking up to a new interest in the education of the whole people, Connecticut must not be left behind.

In this respect the educational policy of New England has always been somewhat in contrast with that of New York. The Empire State, from the first, has relied greatly in education as in politics on the power of eminent leaders in commanding public station. The original creation of a "board of regents of the University of New York," which practically took all education for its province,

implied an authority far more extensive than it has ever been able to use. Later, the State established the office of State superintendency of common schools in 1820. The transfer of this office to the secretaryship of state brought to the service of the schools many of the ablest public men. Later yet, the scheme of supervision was carried out in the appointment of city and county superintendents with unusual powers. But experience seems to have testified that the New England idea of educating the whole people into their duty of instructing the children by vigorous direct local taxation for a local control of the common schools has been most effective. Still, New York has given the country a lesson so attractive in its idea of a concentrated State control of education that Mann and Barnard were moved to laudation of the State as the most progressive in the world in its public policy concerning the schooling of the people.

This circular was followed in July, 1839, by the first report to the legislature from the State board. It was the first thorough, elaborate, and reliable unveiling of the actual condition of public-school affairs to which the people of Connecticut had been treated "within the memory of the oldest inhabitant." Chancellor Kent, of New York, in his Commentaries of American Law, says of it: "It is a bold and startling document, founded on the most painstaking and critical inquiry, and contains a minute, accurate, comprehensive, and instructive exhibition of the practical condition and operations of the common-school system of education." It was not a brilliant discussion of educational theories, although, with the most unsparing criticism of present conditions and methods, the author puts forward the remedy in what amounts to a complete scheme of reformed public instruction founded on the most advanced ideals. Neither was it a public document made up at an official desk from reports, more or less accurate, by irresponsible officials. During the first year of his administration the secretary had literally "stumped" the State. Its extent and population, not exceeding 300,000, with 141 towns, was favorable to the system of minute local visitation, which Secretary Northrope afterwards carried to an almost ideal perfection. Secretary Barnard reports that he had "attended school conventions in all the 8 counties, addressed 60 public meetings, inspected more than 200 schools, consulted with two-thirds of the teachers of the State, and superintended the publication of the new Connecticut School Journal, more than 60,000 copies of which had been circulated during the year."

From the best information it had been learned that of 67,000 children and youth between 4 and 16 only 54,000 had looked in at the door of the common-school house, with only 42,000 in regular attendance; that 12,000 children (of the better-off class) in private schools and academies were costing their families $200,000 more than the entire sum expended on the remaining 55,000, and that at least 8,000 were in no school whatever. But one school society had made a report through its school visitors to the State before 1838. It was exceedingly difficult to obtain accurate information concerning the schools. The public meetings of the school societies were thinly attended and officers frequently elected when no quorum was present. The length of the school term depended on the salary of the teacher. The teachers were rarely examined with any degree of thoroughness, the schools were not supervised, and matters were conducted with constant disregard of the school laws. The schools were often suspended in winter for lack of fuel, which the people were expected to supply in lieu of a rate bill. It was difficult to point at a single model schoolhouse in the State. There was no uniformity of school-books, and primary instruction was greatly neglected in the multiplicity of studies. There was no attempt at the efficient grading of schools, the children of all ages being placed under the charge of one teacher, whose life was liierally a race through a series of brief lessons from day to day. There was no considerable class of trained teachers, and apparently little sense of the need of professional training for the teacher by the secondary and collegiate seminaries.

The irregularity of attendance and constant change of teachers amounted to a

practical waste of the school money. No country and but few city districts supplemented the regulation appropriation of the State fund, $1.25 per capita, by a local tax. The frequent deficit was assessed on the patrons of the schools, often making it as expensive to educate a child in the public as in a private school. The extreme division of the school society into districts and the neglect of the visitors to attend to their duty of supervision left the common school of many little hamlets, as of many city wards, in almost as complete isolation as if located in a dark closet, in no elbow touch with a neighboring school. All the difficulties of the school society were summed up in the existence of a public apathy concerning public-school education, which made attempts at reform almost hopeless. Indeed, this public apathy somewhat accounts for the unanimity of the legislature in passing the laws under the lead of Secretary Barnard. The legislature did not know the people, and it was four years before the people, who were apparently satisfied with this condition of affairs, were sufficiently waked up to inaugurate a reaction which "swept from the statute books in one month all the measures of the State for improvement."

There was no lack of suggestions for the cure of this great infirmity of the Commonwealth. Secretary Barnard's reports for the remaining three years of his administration abound with practical directions for better schoolhouses, uniformity of schoolbooks, the enforcement of their official duty on the school visitors, the just and equal distribution of school money, the necessity of local taxation, the proper grading of schools, with the establishment of free seminaries for secondary instruction. Great stress was laid on the reformation of the present corps of teachers, literally a "dissolving view" of young men working at $15 and women at $6 to $8 per month, "boarding round," flitting "from pillar to post,' often with the best intentions ignorant of the first principles of instruction and wedded to the old hateful style of severe discipline. In the Connecticut Journal of Education, established, edited, and practically supported by the secretary, he published a vast amount of valuable material about the conditions of popular education at home and abroad, in addition to several valuable treatises on instruction, with ample suggestions on all departments of school keeping.

It is unnecessary to follow the indefatigable young reform secretary through the almost incredible labors of the four years of this administration. His entire days and most of his nights were given to his work. As far as present effect on the public mind is considered, it is probable that the literary side of the work was overdone. No people on earth in such a state of educational opinions and practice as the people of Connecticut appear in these tremendous reports would long endure the humiliation of being published abroad through all the world after the style of this terrible "young man among them taking notes." Much of the literature thus launched upon the State during this period in the form of reports, articles in the journals, circulars, and voluminous educational inquiries by the secretary would be lost upon the average teacher. Indeed, these elaborate circulars of questions addressed to the boards of visitors and teachers were enough to "scare the wits out of" their astonished recipients; a sort of judgment-day summons to a style of professional thinking and activity for which they were absolutely incompetent.

The secretary did prevail on the legislature to pass several acts in the direction of reform, and, in 1841, a general codification and revision of the school laws was made. Several towns and cities were aroused to vigorous action; Farmington, Middletown, and Salisbury among the foremost. Dr. Horace Bushnell, of Hartford, himself a host, came to the rescue in a tremendous onslaught upon the condition of the common schools in the chief capital city. But the radical difficulty, the school society organization, could not be reached. The best system of improved pedagogics would fail of effect under such incompetent administration.

To the outside world the State of Connecticut now seemed embarked on a grand

voyage of educational reform. Henry Barnard at once shot up into a national reputation, and was largely quoted abroad. His reports passed rapidly into the realm of educational literature, in many respects the best in the country. Deficient in the great administrative power of Horace Mann; not always accurate in his knowledge of men and reading of public opinion; not, indeed, a politician, but a splendid scholar and an earnest advocate of the best theories of education before the whole country, he was doomed to the supreme disappointment and mortification of seeing his entire educational fabric demolished on the advent of an opposition party to power in 1842. It is doubtful if the administration of Governor Cleveland rightly interpreted the will of the people in this complete overturn of the work of the past four years. But so it was to be. In 1842 Henry Barnard found himself politically "out in the cold" in his own State. The entire code of school legislation with which his name and fame were associated was repealed. His work was generally disparaged and discredited, and the old Commonwealth seemed on the point of returning to "the fleshpots of Egypt" for another generation.

But no effort so consecrated, so forcible, so far-seeing in theory and practical in its application to present needs goes for naught anywhere, especially in a community so accessible to high ideals and good works as the people to whose interest this great apostle of education had devoted his life. Apart from the impulse given to many separate schools and to individuals in full or partial sympathy with his labors, Secretary Barnard had, for the first time in half a century, gathered together a common-school public which ever after could be relied on to further any reform of which a Commonwealth so conservative and cautious is capable. His proposition, at the close of his term of office, to unite this group of people in a general voluntary organization—"The Connecticut Institute of Instruction"—was a failure. But the common-school public of Connecticut was growing in a natural and decisive way. The foremost member of the party responsible for the reactionary legislation now revolted and made common cause with the friends of popular education of every sect, class, and condition. Their first effort was to check the present downward tendency; the second, to gather up the remains of Secretary Barnard's administration into a working policy that should effect his recall to power and set the common school forever on its upward way.

In 1844, two years after the reaction, Governor Baldwin again called attention to the unsatisfactory condition of the common schools of the State, and spoke in high appreciation of the labors of Secretary Barnard whereby "a new impulse had been given to the cause of education." The legislature responded by authorizing the governor to appoint a committee of nine persons for a new investigation, with an appropriation for necessary expenses.

This committee made an elaborate report, probably written by Commissioner Beers, of the State school fund. It opened with a hearty indorsement of the work of Henry Barnard and the State board of commissioners from 1837 to 1842, when "operations were begun which promised to carry our State forward in the cause of popular education—and whose effects are still visible in many places—although the result of this great effort has filled many of the friends of education with despair." The supervision of the schools had already fallen away from what had been achieved in 1842. All the old deficiencies were still present, even that invariable evidence of a low state of public interest in the schools—"the absence of decent outbuildings to the schoolhouse." The general want of interest in the educational training of the children "seems to be the crowning defect, or rather the foundation, of all the evils connected with the schools." The secret of the mischief is distinctly located in the school society. Only 59 of 214 of them had made any return to the questioning of the legislative committee. The report concludes with the statement: "No great change in the system can be introduced at present with fair prospect of success. One fatal deficiency seems to be that the

schools are in politics, and the machinery of one party seems to have been captured by the reactionists, or it may have fairly represented the numerical majority of the people."

But the committee did not leave their task without the suggestion of a policy that effectually "blocked the wheels" of the educational chariot, arresting it at its present downhill route. Two practical measures were suggested. First, that a permanent State official should be given such duties of the former secretary of the board of commissioners as he might be able to perform. Second, that every board of visitors of a school society should be required to elect a chairman, who should be held responsible for the performance of the legal duties of the body. Third, the establishment of a State normal school for the professional instruction of teachers.

These recommendations were adopted, and by the act of 1845 the commissioner of the State school fund was made the virtual superintendent of common schools, with duties similar to those of the late secretary, with the exception of the editorship of a State journal of education. It was the great good fortune of the State at this critical period to have another firm and able official friend of the common schools in Hon. Seth P. Beers, then commissioner of the State school fund. The Commonwealth always had reason to be proud of the admirable administration of its generous school fund under Commissioner Hillhouse and his successor, who now became exofficio superintendent of public instruction. His first report, in 1846, is a modest official summary of the real situation and a moderate suggestion of the virtual reestablishment of the discarded system of 1837–1842.

But the emphasis of the document was wisely concentrated upon a skillful massing of such reports from the school visitors as told on the chief defects of the present system and the publication of an admirable prize essay by Rev. Noah Porter, afterwards president of Yale University, but then pastor of a church in Springfield, Mass. The statistics of school attendance and all matters connected with popular education differ but little from those so thoroughly set forth by Henry Barnard eight years before. In 1845 not a town or school society in the State raised a tax for school purposes by voluntary taxation. In a few cities some $9,000, 10 cents for each child, had been thus collected. In contrast with this record the shrewd commissioner sets forth the progress of the common school in Massachusetts, New York, Michigan, and the neighboring Rhode Island, where Henry Barnard had been called and was now "in the full tide of successful experiment" as superintendent of the new common schools of the little State. In Connecticut "an apathy prevails like an atmosphere of death. People coming from other States to Connecticut feel like coming from the sunshine into a cellar." All the usual agencies of reform agitation were invoked for the awakening of the people.

The call was not unheeded. There was now in Connecticut a growing common-school public, the early fruitage of the seed so bountifully scattered by Henry Barnard and the original board of common-school commissioners, which responded to the appeal in behalf of the children. In 1846 a convention of 250 teachers and friends of the schools was held in Hartford, through four days, organized by Rev. Merrill Richardson, of Plymouth. The following report of Superintendent Beers speaks out with even clearer emphasis demanding a State board of education, the abolition of the school societies, and the resumption of the responsibility for the schools by the towns. It is also suggested that instead of resuming the publication of the State School Journal, the leading newspapers of the State should be utilized and perhaps subsidized for the coming campaign of education; a suggestion so wise that it is strange it has not to a greater extent become the policy of every State. The people are reminded that while the initiation of several of the most valuable reforms in common-school affairs dates from Connecticut, Rev. T. H. Gallaudet, in 1825, having published a valuable pamphlet on normal schools, the school-teachers' institute having been established first in Hartford in

Providence, Newport, and two other settlements. In Providence and Newport and a few smaller towns arrangements for educational facilities were made at an early date, which for many years satisfied the more influential classes, private schools of different sorts and the beginnings of Brown University.

In 1799 the Mechanics' Association of Providence made a vigorous demonstration in behalf of a system of public instruction for the State. Previous to this a movement, inaugurated under the lead of President Manning, of Brown University, for a public school system for the city of Providence, had failed of public indorsement, chiefly because it proposed to subsidize the parochial school of the Friends. Under the energetic influence of Howland, with the cooperation of many of the most wealthy and distinguished people of the city, the legislature in 1799 was persuaded to enact a school law which for the time was perhaps the most enlightened of any in the Union. But it was weighted with two fatal defects, local option and the lack of a reliable superintending State official. Only the city of Providence availed itself of its provisions and founded the system of public schools that has gone on without a serious drawback to the present day. But in 1803 this statute was repealed by the votes of the remainder of the State. Henry Barnard declared that "had this original law been accepted through the State as in Providence, Rhode Island would have had the best school system in New England. Even had there been in the statute a provision by which a competent public official could have explained its provisions to the people, it probably would not have been repealed." It was certainly free from the powerful ecclesiastical influence which indirectly in Massachusetts and more directly in Connecticut prevailed until well into the century.

No further successful effort for popular education was made till 1827–28, when, as the result of an agitation through several years, a school law was finally passed which was practically the basis of the present system of public instruction in Rhode Island. This act provided that the State should appropriate $10,000 annually from the avails of certain taxes and receipts divided among all the towns in proportion to their school population. It also conferred a limited authority on the towns to tax for the cost of instruction. But it left the power to build schoolhouses and school supplies so indefinite that during the next dozen years the statute book was burdened with supplementary amendments, and special legislation was required even to enable a school district to build a schoolhouse. In 1836 the State set aside the United States deposit fund of more than $300,000 for the use of the public schools and afterwards provided for the establishment of district school libraries, and in 1839 legislated to protect children under 12 years of age working in the manufactories by securing to them three months of schooling a year.

But the fatal lack of a central supervising authority left educational affairs still at loose ends. Every little town or school district assumed the prerogatives of a free and independent republic as far as concerned its arrangement for the education of the children. Nobody knew the actual condition of the schools, although the State had then but little more than 100,000 population and some 35,000 children of school age. But in 1843 the public dissatisfaction at this condition of affairs culminated. Governor James Fenner had already declared himself a friend of educational reform, and emphasized his declaration by giving to the schools of his own city, Newport, the sum usually appropriated for the celebration of governor's inauguration day. Strong petitions came up to the legislature. Mr. Wilkins Updike, an influential member, prepared a short bill designed to furnish the one thing needful to set in motion the present cumbrous educational machinery. In a powerful speech supporting the bill, he declared that "outside of Providence and a few towns, the public school system was not a blessing to the State." This speech takes high rank in the educational literature of the Commonwealth.

But in 1843 the public dissatisfaction at this condition of affairs culminated. Governor James Fenner had already declared himself a friend of educational reform, and emphasized his declaration by giving to the schools of his own city, Newport, the sum usually appropriated for the celebration of governor's inauguration day. Strong petitions came up to the legislature. Mr. Wilkins Updike, an influential member, prepared a short bill designed to furnish the one thing needful to set in motion the present cumbrous educational machinery. In a powerful speech supporting the bill, he declared that "outside of Providence and a few towns, the public school system was not a blessing to the State." This speech takes high rank in the educational literature of the Commonwealth.

He freely exposed the unsatisfactory condition of the schools and deplored the fact that Rhode Island, a Commonwealth pledged by its entire history to magnify the personal liberty of the citizen, should be so unmindful of the fundamental personal right of the child to the educational training that makes for good citizenship. Rhode Island was then the seventh Commonwealth in the Union in the scale of intelligence, 1 in 6 adult persons of its population of 108,830 being absolutely illiterate, and the school facilities offered to the children in all respects open to the gravest objections. The best proof that Mr. Updike voiced the prevailing opinion of the progressive school public was the passage of this bill and the invitation to Henry Barnard, just then without official duty by the repeal of the school law of Connecticut of 1842, to visit the State, address the legislature, and generally advise concerning the proper enforcement of the statute.

Dr. Barnard seems never to have been a man even of "literary leisure" during his long life of more than 80 years, four of which have been consecrated to the work of popular education. On the downfall of the system of schools in Connecticut, which he had practically helped organized and administered from 1837 to 1842, he had immediately resumed his travels through the United States, with the especial intention of collecting the materials for a history of the American common school. He was everywhere found carefully observing and wisely suggesting, and everywhere welcomed by the most discerning and influential friends of education. His strong leaning to the literary side of the great revival of the common school had already been manifested in his establishment of the Connecticut Journal of Education, which he had made a storehouse of valuable information. But the governor of Rhode Island spoke the right word when he advised Mr. Barnard "that it was better to make history than to write it." And nowhere in the history of popular education in the United States is there a more conspicuous example of making a new chapter in the history of education than in the labors through five crowded years of Henry Barnard, who accepted and held the office of the first State commissioner of education for Rhode Island from 1843 to 1849.

The Rhode Island school law of 1843 was mainly a provision for a State superintendency of common schools. The first section requires the governor to "appoint an agent," whose salary shall be fixed by the legislature. The remaining clause was a declaration of his duties as usually defined in the few States that had already established the office. Mr. Barnard was appointed commissioner and assumed the duties of the position September 1, 1843.

The immediate duty of the commissioner here, as in Connecticut, was to learn the actual condition of educational affairs. For two very busy years Commissioner Barnard worked at this point in his own characteristic, persistent, and minute style, represented by the daguerreotype, which, according to Hawthorne, most completely reveals the inner life of the subject. Certainly this inspection left on the mind of Mr. Barnard a complete picture of the educational state of Rhode Island, with a thorough insight into the cause of the present state of affairs. In this work of investigation he was favored by the fact that the school commissioner of Rhode Island had in certain ways a larger power than had been conferred by Massachusetts or Connecticut—the appointment of boards of county officials for the examination of teachers and the inspection of the schools.

From 1843 to 1845, when Commissioner Barnard's first written report appeared, he visited every town in the State, and in many cases repeated the visit, inspected 200 schools, and put himself in personal connection with 400 teachers, besides a habit of constant intercourse with parents, friends of education, and even children and youth. One thousand circulars of the elaborate sort that made each a valuable treatise on education had been sent to the teachers and school officials. He was now prepared to tell the people of Rhode Island the facts of the situation in his own peculiar style, in which the most unwelcome truths are pressed home with the irresistible force of a skillful surgeon manipulating a dangerous wound, in a

spirit so appreciative and friendly that his entire career seems to have been free from the fierce personal collisions and violent controversies which finally wore out the life of his illustrious friend and colaborer, Horace Mann.

But the bald facts of the case were sufficient to wake the most apathetic people to a sense of impending peril and were in themselves a loud call for reform. The school legislation of the State had become a bewildering maze, the original law of 1828 having been so built upon and modified, with so much left to special enactment, that the system was almost unworkable. More than fifty supplementary acts had placed the original statute like a house located in the center of an everglade through which only an expert guide could find the way. The law was a fair transcript of the state of public opinion in the little Commonwealth. Everywhere private and personal opinion, masking under a lofty assertion of "independence," "had full course to run and be glorified." The original Providence compact to obey the government of the majority "only in things civil" had been perverted so that education by the State was supposed to violate the religious liberty of the parent; a curious illustration of the way in which the narrowest religious sectarianism may fraternize with the most radical assertion of civil and religious liberty; as the deadly rattlesnake and the harmless gopher of the Western prairies burrow in the same hole. So violent was this prejudice that respectable members of the legislature declared that the attempt to tax a community for public schools "would be resisted at the point of the bayonet."

The evil of local division into little school districts had practically made good school keeping in the open country an impossibility. The State was swarmed upon by discarded teachers from abroad, and there was no attempt at professional training at home. The neglect of the examination of teachers, school visitation, and supervision was even an exaggerated copy of what the commissioner had encountered in Connecticut. The variety of schoolbooks on every topic was numbered by the hundred, and there was great neglect by many parents to furnish the children with books at all. In 1844 but three towns had imposed a tax for schools. In 1845, outside of Providence and a few smaller towns, there was not three months a year of school. One in every forty of the adult people of the State could not read or write. Mr. Barnard found only twelve female teachers in the State outside of Providence and a few towns. He asserted that two-thirds of the children could be taught better by women, and their employment at regulation wages would add two months to the winter school term.

The condition of the schoolhouses was such as, by contrast, to make the present status of school accommodations "palatial." In 1843-44 only 312 houses were provided for 405 schools, 147 of them being owned by "proprietors"—virtually private property. Of 280 examined, 25 "were in good repair," 62 "in ordinary repair," 86 "absolutely unfit for occupation," 180 "on a line with a public road," 29 only with a playground, 200 had an interior height of only 8 feet, with no means of ventilation; the seats were generally arranged around three sides of the room, with no backs, and 14 to 18 inches above the floor; "270 had no clock, blackboard, or thermometer, and only 5 possessed a scraper or mat for the feet."

In 1844 there were probably 35,000 children between the ages of 4 and 16 in the State; 24,000 were in all the schools—21,000 in public and 3,000 in private; only 13,500 in regular attendance. Only 5,000 attended during the whole school year, 6,000 not over three months. The school boys outnumbered the girls, above 16 five, and above 10 years of age, four to one. Six thousand children had no regular schooling. Mr. Barnard declared that four-fifths of the private schools would disappear if the public schools could be improved. Only 2,000 of the 35,000 children received nine months schooling in the year.

In short, all the defects with which Mr. Barnard had struggled during his five years administration in Connecticut were found in an exaggerated state in Rhode Island. But the small area of territory, the concentration of population in a few

centers, the entire population of the State being less than the city of Providence to-day, and the whole number of children not exceeding that of a city of 200,000 people, were favorable circumstances. Some of the most serious obstructions in Connecticut did not there exist. In Mr. John Kingsbury, principal of the famous Academy for Girls, in Providence, the commissioner found an able and indefatigable assistant. In 1845 the Rhode Island Institute of Instruction was formed, which became a powerful agency for missionary work. For several years it maintained an "itinerating agency" in the person of Mr. Baker, which amounted almost to a house-to-house visitation. The journal of the institute, edited and largely supported by Mr. Barnard, became the medium of publication for his reports and information concerning public education at home and abroad.

In 1844 the legislature intrusted to Commissioner Barnard the preparation of a new school statute. The work included the codifying and rearranging the school legislation of the State. This law, after two years, was adopted, and by 1848 the school-ship was in full sail toward the haven of success. One valuable service to the people was an elaborate explanation of the new law, prepared by Mr. Barnard, published with it, and sent to every school district. In this law and commentary the defects of the schools received attention, and as far as possible were remedied.

The result was that when Mr. Barnard was compelled, in 1849, to retire from his office by failing health, he could honestly report that Rhode Island possessed one of the best systems of public education in the Union. One hundred and twenty thousand dollars outside of Providence had been expended in building or repairing schoolhouses, and the commissioner's valuable treatise on school architecture was in the hands of every school committee. Every town in the State raised a tax to supplement the State fund, and the local levy amounted to $1 per capita. More than 1,100 meetings had been held and 1,500 addresses delivered, beside a perpetual discussion of educational topics.

A large convention of school officials and eminent teachers had met, after nine months' experience of the new law, to discuss its merits and suggest amendments; 200 meetings of parents and teachers had been held; 16,000 educational pamphlets, each of 16 pages, had been gratuitously distributed, and 1,200 volumes bought by teachers for libraries. During one year every almanac published in Rhode Island had contained 16 additional pages on education, furnished by the commissioner. A school library of at least 500 volumes was found in 29 towns.

The improvement in school buildings was pronounced "a complete renovation, nay, a revolution," the State in 1849 having the best average of schoolhouses in New England. "Good teachers and improved school buildings had added 50 per cent to school attendance." One hundred primary schools with women teachers had been established, and the graded system was organized in all the principal towns. No schoolhouse was without a blackboard and one-third of them had globes and maps. The best people in the State were serving on school committees, and the new school law imposed a fine for the refusal to serve after election. The towns had been granted an unlimited power of local taxation, a minimum rate being fixed as a condition of receiving the State distribution. In 1847 only three towns in Rhode Island refused to vote a tax for schools. The entire expenditure for public education was $58,000, more than one-half the entire expenses of government for the State. The valuation of the State in 1844 was $59,000,000, the largest per capita in any State, $5.41; Massachusetts, $4.06; Connecticut, $3.25; New York, $2.49.

But there was still a great work to be done in Rhode Island. The conditions, even after the great results achieved by Mr. Barnard's administration of five years, were such as would not be regarded with a special favor in any State of the Union to-day. But the decisive battle had been fought and won. The people of Rhode Island had learned the great lesson of cooperation for the public good, and the reign of unbridled personal and private opinions and obstinate willfulness

masquerading as the spirit of freedom had closed. It was most remarkable. On the retirement in 1848 of the great commissioner, enforced by a collapse of health induced by his great exertions in behalf of the children of the State, the legislature unanimously enacted a vote of thanks, the teachers of the Commonwealth expressed their gratitude by a valuable present, and the portrait of Henry Barnard now hangs in an honorable place in one of the public buildings of Providence.

THE COMMON SCHOOL IN CONNECTICUT.

But while Mr. Barnard was thus occupied with the creation of the first common-school system of Rhode Island his heart was still in his own State and city. One of the most important of the many good works accomplished in these early years of his prolonged ministry of education was the great influence and aid he contributed to the protracted effort to establish the Free High School of the city of Hartford, Conn. In a remarkable letter to Principal Capron of this school, written in 1871, he gives an elaborate history of the campaign of education through which this celebrated school fought its way to its final establishment, becoming as great a power for the free secondary education in Connecticut and other States as Yale in the realm of the higher education. As an object lesson in the history of multitudes of similar institutions in all parts of the country, and an encouragement for the persistent and intelligent pushing of a great public cause, this letter could be republished and read to-day, especially in our Southern States, with great benefit. A brief sketch of this episode in the busy life of Dr. Barnard should not be left out of this narrative.

In the speech delivered by young Henry Barnard, as a member of the legislature of Connecticut in 1838, in support of his own bill for the reform of the depressed school system of the old Commonwealth, occurs a hearty tribute to the Boston Latin School, first and most celebrated of the class of free seminaries of the secondary type that came up in connection with the original common-school movement in the New England colonies. He tells the story, more striking then than to-day, that in this school a son of a President of the United States received the second prize, when the first honors were given to the son of the man who sawed the President's wood pile. Soon after his appointment to the office of secretary of the Connecticut State board of education, in an address before the Young Men's Institute, or Lyceum, of Hartford. Mr. Barnard urged the young men to labor for the development of the higher city life, including a reference to the unsatisfactory condition of the public schools of Hartford. This lecture in substance was repeated in several of the larger towns of the Commonwealth, and is said to have been very influential in the movement that resulted in the establishment of high schools, public libraries, and similar institutions in the State. Among other suggestions was one that has commended itself to many of our chief American cities and smaller towns—a voluntary association of mothers to look after the sanitary arrangements and moral training of school children. In this admirable address he outlines the present system of agencies for the general welfare of our larger American communities with a prophetic foresight. It is suggestive of the state of public opinion in New England half a century ago that, even as late as 1838, an educator so progressive as Henry Barnard should have been obliged to advocate the schooling of the free colored children of Connecticut in separate schools.

In 1842, on his retirement from the administration of the discarded system of education in Connecticut, Mr. Barnard prepared a document as an appendix to his final report urging the addition of the free high school to the present system. Although this was only a call for the restoration of a prominent feature of the original colonial common school, the free grammar school to be established in every town of 100 families, the legislature of Connecticut refused to pass it on the plea that it was inexpedient to support the secondary education by the State. At

this juncture Mr. James Wadsworth, of New York, a native of Connecticut, already known for his munificent and influential support of the district school library system in his adopted State, caused to be printed and circulated at his own expense 30,000 copies of Mr. Barnard's document, which was largely read and was very influential through the entire country.

Previous to this, in 1839, at an educational convention held at Hartford, presided over by Mr. Seth P. Beers and addressed by Prof. Calvin Stowe, Alexander Everett, and George B. Emerson, the subject of the grading of city and village schools was thoroughly discussed at several sessions, every city of the State being represented. Mr. Barnard there urged the establishment of union schools. Professor Stowe then asserted that the public schools of Cincinnati, Ohio, were among the best in the country. It was shown that five-sixths of the nonattendance on the common school was in the cities and larger towns, probably from the fact that these were the manufacturing centers of the State and the well-to-do families educated their children in private schools. It was suggested that private associations might well be formed to agitate for and, if necessary, to afford material aid to this enterprise. This was effectually done a few years later, at New Britain, Conn., in the establishment there of a State normal school. An association of this sort was formed at once at Hartford; at first of five members, two more than the attendance at the last annual meeting of the Central School Society of that city.

The agitation thus begun did not pause till six years later it resulted in the establishment of the Free High School for Hartford for boys and girls, with the old Hopkins School of the city included as its classical department. The long and obstinate conflict that terminated in this victory for the people was one of the most influential in the history of American education. The staid old capital of 10,000 people was shaken to its rock-ribbed foundations. Dr. Horace Bushnell, the splendid man of all work for Connecticut, as the foremost theologian of America, in 1842 contributed an important service in his scathing exposure of the condition of the public schools of the city, and his energetic appeal led to a reorganization of the central school society, out of which, in 1847, came the present high school. Before that time, in 1839, Mr. Barnard began the publication of his Connecticut Common School Journal, without a subscriber or a dollar of income, and supported it chiefly by his own money.

In 1842 the cause of popular education gained a new and powerful advocate in Mr. James N. Bunce, a gentleman of large wealth and public spirit in Hartford. He had attended an educational convention in 1845, where, before a meager audience, the most important matters had been ably discussed, and declared that "this should not happen again if he could help it." Another convention, more largely attended, was held in 1846. Mr. Bunce wrote to Henry Barnard, then in Rhode Island, to "come out of the wilderness and help your own brethren and State," promising his own personal cooperation and material aid. Mr. Barnard in reply suggested that he was just then too much occupied in "making the wilderness blossom as the rose" to accept the call. But he at once took the matter to heart, proposed a campaign of agitation, and for the five subsequent years was the soul of the movement.

At his suggestion Mr. Bunce offered a prize for an essay on popular education, which brought forth the remarkable paper by Rev. Noah Porter, afterwards president of Yale, which is still a classic in American educational literature. Mr. Barnard made a statement which the teachers and educators of the country would even to-day do wisely to heed: "I have never seen a gathering of parents of any class who could not be interested in the subject of schools and education if presented in a practical way, and especially in reference to their own children and schools." Thus through a five-years' campaign, not inferior in spirit and exciting incident to a great political election, the people of Hartford, as far as concerned

the voters of the central school society, were at last educated to the point that, after repeated meetings and months of public discussion, the vote was carried by an overwhelming majority for a free high school. Mr. Bunce contributed $1,000 toward the expense and pledged $5,000 toward a State normal school. Twelve thousand dollars was invested in the enterprise and the Hopkins grammar school fund provided for the classical department. A tax for 1¼ cents on the dollar was laid on the property of the members of the society for its maintenance. It at once became one of the best of this class of seminaries in the country. Mr. Barnard visited Hartford five times in connection with it, engineered the campaign, outlined the plans of the building, drew up the course of study, and was, in fact, almost omniscient in the good work.

On December, 1847, he was called to the grateful task of assisting at the dedication of the new high school at Hartford. In his address, which also covered every superior interest of the metropolitan life of the country, he made the remarkable declaration: "I say deliberately, for the whole country, that if the efforts which have been put forth here, and which the deep conviction of the same necessity has caused to be put forth in other States, fail to incorporate this high school feature into our system of common schools, that the higher education—everything beyond the merest rudiments, will pass into the inevitable keeping of religious bodies and adventure schools, over which the people can exercise no control, and parents can have no guaranty of the value of the education their children will receive. There can not be—there never has been—an efficient system of primary instruction, whose teachers and officers were not supplied from public institutions of a higher grade."

On this occasion Dr. Horace Bushnell also delivered one of those remarkable addresses which so often during his prolonged career set the most thoughtful people of the entire Republic thinking along new lines of observation. The occasion was one long to be remembered. It is not too much to say that the establishment of the Hartford free high school marked a new era in the development of public secondary education in the country. It was the most signal victory yet achieved in the conflict everywhere inaugurated between the people and the religious sects and more favored classes for the control of this important department of education. This school at once became a conspicuous center of the secondary education for the whole State, and thirty years later remained a great academy to which pupils were sent from all portions of the country.

Its establishment was also the stimulant to a similar movement in other cities of the Commonwealth. A few years later Dr. Barnard was called, as one of a distinguished group of college presidents, professors, and public men, to dedicate the free academy at Norwich, Conn., whose reputation has only been less than the Hartford High School, and whose outcome has been the elevation of this and many of the smaller New England cities to national reputation as centers of educational and philanthropic activity. Norwich is now everywhere known in connection with the schooling of the colored youth of the South in normal and industrial training, by the gift of the Slater fund of $1,000,000. Connecticut from that time, even beyond its previous reputation, became a great hive, sending forth every year new swarms of enthusiastic workers in the secondary and higher education, especially through the West and the South. The influence of Barnard, Capron, Gallaudet, Porter, Bunce, Bushnell, and Beers was felt at once even to the summit of the great mountain divide, and later through our new Pacific empire.

In his letter to Principal Capron, Mr. Barnard, in 1871, wrote this triumphant declaration: "I have seen every provision drafted by me, which was stricken out of the statute books of Connecticut in 1842, restored, and many more remembered by me not only placed in the school laws, but also become a part of the school habits of the people. And more than this, I have lived long enough to see nearly

all the condemned features of city and town organization advocated in Hartford from 1838 to 1842 and denounced as the 'impracticable schemes of an enthusiast' ingrafted into the constitutions of 15 States and the school systems of 35 States and upward of 100 cities of over 40,000 inhabitants and many more with a smaller population." What a supplement could this venerable apostle of the people's school write to this declaration now, twenty-five years later, when he beholds the majestic spectacle of our 16 Southern Commonwealths united in the support of every department of the people's common school, with a dozen new and powerful States and Territories beyond the great mountains and along the Pacific Coast, each in some good way surpassing its predecessors in the glorious work of training its children and youth for the coming citizenship of the new Republic.

But even in this letter to Principal Capron, Dr. Barnard notes the fact that Hartford, as late as 1871, still held with a firm grasp to the antiquated local district organization of the common school. Half the children in the city, according to his statement, were not then found in it. And later than this, the original system of separate district organization was persisted in after it had disappeared from almost every other city of similar importance in the Union. The educators of our new States, who rejoice in the organization and growth of their splendid systems of public instruction, can with difficulty realize through what a long and wearisome period of toil, conflict, and sacrifice the great apostles of the children and youth wrought through the generation of the common-school revival, from 1830 to the opening of the civil war, to save this, the nation's most precious heritage, for its future perpetuity and glory.

HENRY BARNARD AS STATE SUPERINTENDENT IN CONNECTICUT.

On the 1st of August, 1851, Henry Barnard was recalled to his former position, now fitly named superintendent of the common schools in Connecticut, and at once entered on the duties of a second term of four years. It will be unnecessary here to enlarge on the performance of the ordinary official labors of the new superintendent during this period. The actual condition of the public schools of the State was not greatly in advance of what has already been set forth in 1842; indeed, it is possible that in some localities they had suffered from the repeal of the law of 1838. But in several important conditions of success there had been a marked improvement. The spectacle of a great political party using the temporary disaffection of the people concerning popular education to elevate itself to power is always a warning to an American Commonwealth. In this case the warning seems to have punctuated a crisis in the common-school policy of Connecticut.

At once the friends of the educational revival and reform came together as a proper educational public, which, by 1844, made itself felt at the statehouse and in the administrative affairs of the Commonwealth. It can not be denied that the marvelous intellectual fertility of Henry Barnard, as the foremost American literary exponent of the great revival of popular education, was somewhat in the way of immediate practical results in reforming abuses and inaugurating radical changes in the schools. His successor, Mr. S. P. Beers, brought to his difficult position the rare executive ability which had characterized his administration of the State school fund, and, through his cautious and persistent handling of the legislature and wise direction of public opinion, one of the most essential features of Dr. Barnard's policy, the establishment of a State normal school, had been already brought to a happy conclusion.

The establishment of the first teachers' institute in Hartford, in 1839, during the administration of Secretary Barnard, was followed by a vigorous working of that important agency. Every year during the administration of Mr. Beers this popular movement had gained strength, until it secured the favor of the teaching body

and impressed the thoughtful class of the people with the idea of a permanent arrangement for normal instruction. For thirty years the more progressive leaders of public education in Connecticut had been laboring at this problem. In 1816 Mr. Denison Olmstead, then principal of the Union School at New London, had published an important pamphlet on "An academy for teachers" and reenforced its arguments in a striking address at Yale College. Prof. J. L. Kingsley, of Yale, in 1823, through a forcible article in the North American Review, had discussed the same proposition. Dr. William Russell, principal of the New Township Academy at New Haven, had given his influential name to the agitation. In 1825 Rev. T. H. Gallaudet, already with a national reputation as the leader of the important department of the education of the deaf and dumb in the United States, wrote a series of able articles on normal school instruction, which was republished and widely read. Dr. Barnard declares it the crowning service of Dr. Gallaudet to the cause of American education, that not only in his own specialty but in the general application to all schools he so ably and distinctly set forth the necessity of special professional training as a prime condition of success in the fundamental profession of instruction. We have seen that Dr. Barnard, in his notable legislative speech before the general assembly, which carried the original reform-school law of Connecticut in 1838, declared that a special provision for the training of teachers was a vital part of his proposed reform in the common schools of the State. He vigorously followed up this proposition in all his reports as secretary of the State board of education. In 1839 he carried a bill to appropriate $5,000 for the general work of training teachers, not necessarily for a State normal school, through the lower branch of the legislature, only to see it practically shelved by a committee of the senate. His repeated attempts to push the subject, in 1841, met the same fate. In 1842 the work was arrested and his office abolished by the repeal of the law of 1838.

But the good seed thus sown during a generation had fallen on good ground and sprung up. The teachers' institute was the form in which both the school men and the public now welcomed the movement. Many prominent educators from other States and men of large public reputation at home were brought before the great audiences that thronged these gatherings.

In 1844 a committee of eight was appointed to investigate the condition of the public schools. This committee, at the session of 1845, made a report including the recommendation for a State normal school. In 1846 (S. P. Beers, secretary) the legislative joint committee on education reported a bill appropriating $2,500 a year for four years to establish a training school for teachers, with a committee of eight, one from each county of the State, to locate and establish it. The proposition was warmly debated and the bill passed unanimously in the house, but was lost in the senate by one vote. But in 1848 the bill finally became a law. After a ten-years battering at the "knocker on the big front door" the "land of steady habits" admitted the State Normal School for teachers. The people of New Britain, a pleasant town a few miles from Hartford, at once formed an "educational fund association," with a capital of $25,000, in shares of $25, to locate the new normal school.

On June 4, 1851, the State of Connecticut joined the procession, third in the line, with Massachusetts and New York ahead, in dedicating the new normal school buildings at New Britain. The people of that town had erected school buildings at the expense of $16,000, and placed their own schools with several hundred pupils under the supervision of the normal as a school of observation and practice. Henry Barnard lately retired from his arduous and brilliant career of supervision in Rhode Island, was now brought back to his native State and city in the double office of "superintendent of public education" and "principal of the State Normal School." He accepted on the condition that a competent assistant should have the special charge of the normal school, and Rev. T. P. D. Stone, from

Massachusetts, was called, with the aid of Professor Guion and several assistant women teachers, to this post. Two of the early teachers of this first normal school in Connecticut, Dr. Philbrick and Mr. S. D. Camp, afterwards became the successors of Dr. Barnard in the State superintendency.

On a midsummer day, June 4, 1851, the governor, State officials, legislature, and a goodly show of the foremost citizens of the State, with an imposing military demonstration marched to the railroad station at Hartford and were received at New Britain with added ceremony by the enthusiastic people of the enterprising little New England town for a whole day's and evening's celebration of the opening of the State Normal School. In his address, Superintendent Barnard again took up the theme on which, for the past sixty years, he has told his "story without an end," of education as the glory of the Republic. After a mighty feast of Connecticut roast turkey, mince and apple pies, the great crowd surged back to "business" and listened for another hour and a half of a summer's night to one of the electric discourses of Dr. Horace Bushnell, for a generation the theological and spiritual dynamo of New England, on "Connecticut." The school had already been opened with 35 pupils, and 300 applied during the first year. For two years the State Normal was little more than a permanent normal institute, receiving teachers and pupils of all grades for even less than one term, with personal courses of study. Its sessions were adjusted to the convenience of the terms of the summer and winter district schools. But the organizers of the New State Normal with wise discretion had planted it amid the environment of a large practice school, containing the entire school population of a considerable town, officered by experienced teachers, and the observation and practice in a good graded school was of inestimable benefit, even to the crudest young schoolmaster who came up for three months to New Britain, as to an educational Mecca, for aid and comfort. But in the third year the legislature voted a permanent annual appropriation of $4,000, and a systematic course of instruction was set up at the center of the drifting crowd of students. In 1860 State Superintendent Camp reported gratifying progress. Already, in less than ten years, 1,500 teachers had come under the influence of the State Normal School from 130 towns, 500 of whom were then in service, at least one from every school society. Dr. Barnard was unable, from his arduous duties of State superintendency, to secure time for instruction in the school, or even do much for the institutes, although his fatherly eye was here as everywhere upon the children and youth of his beloved State.

Another most important service rendered to the Commonwealth by Superintendent Barnard was the drawing up of a revised code of school legislation, which included all the reforms he had originally advocated. After a sort of informal "referendum" to the teachers and people and a thorough discussion in the legislature it was enacted in 1849. It aimed, in general, at a consolidation and simplifying of the entire organization and administration of public school affairs. As far as was then possible it attempted to restore the management of the common school to the control of the towns, the reduction of the too numerous school officials, the more equitable distribution of the State school funds, the encouragement of local taxation and especially the inauguration of the graded system whereby the inevitable confusion of the oldtime district school of New England was brought into order by the classification of pupils according to their attainments, and the building up of the present scheme of instruction from the primary to the high school adopted.

Under the overloaded system then in operation, according to Superintendent Barnard, "each of 1,650 school districts was independent of all others and practically acknowledged but a loose dependence on either the school, society, or the State." Not less than 10,000 school officials, 2,000 of them, according to the same authority, absolutely incompetent, and the majority indifferent to or neglectful of their legal obligations, were muddling the education of 75,000 children. Here, as in Rhode

Island, was the real laboring oar of the educational craft, to break up the obstinate Puritan conceit of local independence in public affairs under which the most important concern of the State was practically falling into the hands of little rings of officeholders, even elected frequently by less than a quorum of the society meeting.

But another service was not less important to the general educational welfare of the State and nation—the preparation by Superintendent Barnard of "The History of the Legislation of Connecticut Respecting Common Schools up to 1838." In place of an ordinary report for 1854, the superintendent furnished a stout volume of 180 pages of closely printed matter, not merely a dry record of legislation, but an elaborate and eloquent history of popular education in the State that, up to a recent time, had been in several important respects the most complete object lesson of the American common school in the Republic. Along with this were printed several valuable supplements and a useful sketch of educational affairs in all the States which at this time had made any considerable progress in the common school—New England, New York, and Ohio. This document, with the reports of Horace Mann and Henry Barnard, was the real beginning of the educational literature of the common school in our country. It was followed by a long procession of similar documents, State and national, in all parts of the Union. Out of this has come a body of common school practical literature for the uses of a republican State more valuable than that of any other country or period, where all that has come to us from abroad has been considered and its adaptation to local and general needs for the training of good American citizenship retained. Out of it came up, in 1865, the National Bureau of Education, now in practical efficiency the undisputed head of similar departments of education. Along with this, Superintendent Barnard had published and contributed, somewhat from legislative grants, but to a great extent at his own expense, many thousand copies of important documents concerning education abroad, schoolhouse architecture and arrangement, normal schools, and improved methods of instruction which, often republished, had revealed him more and more to the whole country.

All this is but an inadequate view of the vast upland region of the twelve years of school administration and authorship which declared Henry Barnard the nation's man of all work in the cause of the children. As usual, in all similar undertakings, he was again prostrated by shattered health and retired from the position of superintendency in 1855. His successor, Dr. John C. Philbrick, was called from the principalship of the State normal school to the position. In the opening sentences of his first report, 1855, he speaks of his predecessor in these eloquent words: "I can not forget that I occupy the place that has been filled by one whose eminent abilities, wise counsels, and abundant labors in the cause of popular education have merited and secured the highest respect and confidence of the people of the State. He embarked in this enterprise of superintendence when there were few to encourage and aid and many to discourage and oppose. He had peculiar work to do. He had to encounter the jealousies of party, the prejudices of ignorance, and the hostility of a blind though honest conservatism, which could see nothing in his plans of improvement but destruction to the old landmarks of the fathers. In retiring he leaves a different state of things. He has enjoyed the satisfaction of witnessing these obstacles gradually melt away before the power of truth and the friends of progress constantly increase in number and power, until his long-cherished hope of seeing Connecticut regain her ancient place in the first rank of the educational States seems about to be realized and that blessed day is ushered in when every school in the State should be good enough for the best and cheap enough for the poorest."

But the old State of Connecticut still went on, in Yankee parlance, "at her own jog," through all this tempest of literary and executive activity for the better educa-

tion of the Commonwealth. In 1852, fourteen years after the revival of 1838, Superintendent Barnard reports the condition of public education as follows: There were 148 towns and 6 cities in 8 counties. Population of State, in round numbers, 375,000, with a property valuation of $170,305,000; 95,000 children of school age (4 to 16); 217 school societies; 1,652 districts; State school fund, $2,050,000, with an income of $133,000, $1.40 for each child; town deposit (United States) fund, $763,600, with income for use of schools, $30,000; society and local funds, $100,000, with $6,000 income; tax in these societies, $4,000, and in 17 districts, $10,000; income from rate bills, $20,000, and from fuel tax, $10,000; in round numbers, $200,000 for cost of schools; 1,500 districts had winter and 1,400 summer schools in session from sixteen to forty-four weeks in the year; 75,000 children were enrolled, with an average attendance of 52,000; 8,400 pupils were found in 410 private schools, at a cost of $164,000; nearly three-fourths the sum expended for the 8,400 pupils in private as for the 75,000 children in common schools. More than 1,700 teachers received, for men $18.50 and for women $8.22 per month. Only 270 of these taught the same school in summer and winter, and 570 were teaching with no previous experience. Sixty schools had been "broken up" during the year from incompentency of teachers. Nearly one-half the teachers were "boarding round." Of the schoolhouses, 240 were reported "very good," 460 "very poor," more than one-third without sanitary arrangements for common decency. The reports of the county inspectors, appointed by the superintendent, are full of complaints of "popular apathy." A notable Fast Day sermon, by Rev. Mr. Goodrich, of Bristol, concentrated these defects of the system in a powerful and earnest appeal to the people, which was republished as a portion of the report of Secretary Barnard.

But much had really been done: A true educational public had been aroused; a body of efficient supervisors and educational workers had appeared, evolved by "natural selection" from the teachers and writers who were often better known and more influential outside the State than at home; a majority of the teachers were being gathered into the annual institutes and the State normal school; a State and several local associations were waking up the people at their numerously attended meetings addressed by the ablest school men from abroad and at home; an improved code of school laws had been spread on the statute books and the way at least opened for the proper consolidation and simplifying of the school life of the Commonwealth. And more than ever the fame of the great educators of Connecticut had been spread abroad and often with a better reception than at home were they received and put into active school life, especially in the new and growing States of the West. Meanwhile, New York, so largely dependent on Connecticut for the early establishment of her common schools, was now so far advanced that both Horace Mann and Henry Barnard magnified the Empire State as the foremost educational Commonwealth in the world.

Among the eminent men in Connecticut to whom Henry Barnard was greatly indebted, not only for constant aid and comfort during his eventful career of superintendency in his native State and Rhode Island, from 1838 to 1855, but for perpetual suggestions in his philosophical and practical ideals of education, was Rev. Thomas Hopkins Gallaudet. But, far beyond his great contributions to his own State, was the influence of Mr. Gallaudet felt through the whole country; directly as the leader in the education of the deaf and dumb and indirectly for the reformation of the methods of primary, mental, and moral instruction by his grasp on fundamental principles and scientific methods thereby obtained.

This admirable man came into the world with a furnishing of heredity that was in itself an assurance of greatness. He was of a good Huguenot French strain, blended with a descent from Italy running up to a superior class of Venetian ancestors, reenforced by a vigorous Scottish and the best of Puritan blood. Thus furnished, he seemed destined from his cradle to that finest blending of Christian fervor, physical sensibility, pedagogic aptitude, and invincible will that

was the inspiration of all he did and of much that from the hindrance of delicate health he could not achieve during his crowded life of 63 years.

His father, after a varied life in Philadelphia, New York, and Hartford, was drifted into Government employment at Washington, where his grandson now presides over the National Asylum for the Deaf and Dumb, and there died at an advanced age. Among other good things, he established in his eightieth year, in 1835, "the Washington Manual Labor School" and "Male Orphan Asylum." Its expenses were heartily met by the unique work, "the facsimile of George Washington's public accounts while commander of the armies of the thirteen colonies during the Revolutionary war." The institution was afterwards merged with the Deaf and Dumb Asylum before mentioned.

Thomas Hopkins Gallaudet was born in Philadelphia in 1787, the oldest of a family of twelve children. He was fitted for College at Hartford, Conn., and entered Yale as sophomore at the age of 15, graduating in 1805 with high honors; President Heman Humphrey, of Amherst College, and Dr. Gardiner Spring, afterwards of New York, being his associates in class distinction. Yale was then under the presidency of Dr. Timothy Dwight, with Professors Day, Silliman, and Moses Stewart in the chairs of instruction. Like Barnard, he entered on the study of the law, but after a year was compelled by failing health to seek an outdoor life. As the "traveling man" of a New York commercial house he visited large portions of the West and Southwest, and afterwards was connected with the firm in a New York counting room. From this occupation he was drawn by his strong leaning to the life of a clergyman and entered Andover Theological Seminary, from which he graduated in 1814. Declining several flattering offers for a permanent settlement in the ministry, he returned in 1814–15 to Hartford.

Here, at the age of 28, he was found awaiting the providential call of his life. A little deaf and dumb daughter of Dr. Mason F. Cogswell, a distinguished physician of Hartford, was "the little child that led" young Gallaudet to the strangely neglected but wide and rich domain of education in which he won a national fame and achieved abundant success. In the attempt to teach little Alice, his attention was directed to the reputation of the three English schools of this sort, and especially the writings of the famous Abbé Sicard, of Paris. Up to the year 1800 there was no knowledge of such a department of education, and in 1815 but one small school of the kind in America. His success with his little pupil woke up a lively interest, and an association of leading gentlemen furnished the moderate means for a short visit abroad of observation and instruction.

In the summer of 1815, Gallaudet, a Connecticut young man in pursuit of information on a great subject, appeared at the front door of the Institution for the Deaf and Dumb in London asking for admittance. But, with the true spirit of British isolation and exclusiveness of that period, the training of the deaf and dumb was a private monopoly, and he could not obtain the privilege of admittance, much less of instruction, except under conditions so humiliating that to receive it would be a positive degradation. Failing in the same way in Edinburgh, after making several valuable acquaintances, like Dr. Chalmers and Dougal Stewart, he went to Paris, where he was welcomed at the institution of the Abbé Sicard. After several months of close study he returned to Hartford, accompanied by Mr. Laurent Clerc, an experienced deaf and dumb instructor, who during the remainder of his long life was the soul of the new institution which he entered in 1817 as assistant, though really the instructor of Mr. Gallaudet. During his residence in Paris he preached in an English church, and his discourses, afterwards published, showed that in the profession for which he had been educated he would have become one of the lights of the American pulpit. Beside a small establishment in Virginia, there was at this time no institution of the kind in the country.

Through the influence of a group of the best-known men in Hartford, a subsidy of $5,000 was obtained from the Connecticut State legislature, and afterwards

$17,000 gathered by the exertions of Mr. Gallaudet in several cities. In 1817 he entered upon his notable career of fourteen years as principal and teacher in the Hartford Asylum for the Deaf and Dumb. Through his own appearance before the Congress of the United States an appropriation was made of a grant of 23,000 acres of public land, from which was realized a permanent endowment of $300,000 for the institution. It was dedicated with the usual solemn public ceremonies by which New England always loves to inaugurate a good work of education, philanthropy, or religion on May 22, 1821.

The first pupil was Alice Cogswell, and the fifteenth Julia Fowler, whom Mr. Gallaudet married in 1821. She lived fifty-six years and proved herself a true helper in all the relations of his home and public life. It was soon discovered that the new principal was, in the words of his son, "a born teacher, and a teacher of teachers as well as of children." He made a wonderful success in the development of the language of signs to which he was devoted. Like other specialists, perhaps he did not quite distinguish the fact that his own success in this was inseparable from his personal genius rather than from its general use and practicability. It is said that at the request of the famous Connecticut painter, Col. John Trumbull, the story of the condemnation to death by Brutus of his two sons was entirely communicated by facial signs so correctly that a pupil wrote it all out. His biographer finds in this a trace of his descent from an Italian ancestry.

But, as so often happens, this man of commanding genius, at once known and acknowledged through the Republic by his labors in several States as the founder of similar institutions, was compelled to live the life of a pedagogic drudge at home. At the end of a chronic state of friction with his board of directors concerning details of administration he felt compelled to retire from the institution, after fourteen years of a service that, despite his habit of self-sacrifice, rendered him a perpetual subordinate. But, as a member of the corporation, his advice and aid were always at the service of the institution. His policy of administration was finally adopted, and in later years, at a great gathering of 400 graduates and pupils of similar asylums, a remarkable memorial service was held with the usual gift of professional silver. To-day his monument, built by the contribution of pupils and graduates of asylums, stands in the grounds of the original institution at Hartford, and a similar memorial may be seen at the national asylum at Washington, which was established largely by his influence and is now presided over by his son.

But this was not the only instance where a man of commanding genius has been "retired" upstairs by an unappreciative community into a broader sphere of his life work. In 1830, at the age of 43, Rev. T. H. Gallaudet was without question the foremost man in his own specialty in the United States. But for the twenty remaining years of his life he stood before the whole country as one of the broadest, most original, and practical of American educators, in the best sense of the term. Declining repeated invitations to almost every conceivable position of honor and profit in education, philanthropy, and the Christian ministry, he gave himself for eight years to the work of educational authorship. He had already become known by his numerous contributions to the coming educational revival, especially by a series of letters on the normal training of teachers in 1825, and other writings in support of common schools. His profound studies in child-nature applied in the training of the deaf and dumb had brought him into the very arcana of the philosophy of the natural methods of instruction, now a recognized authority in all schools, and his contributions to this most attractive realm of pedagogics were perhaps more valuable than those of any American educator of that period. The children of to-day, whose most exciting mental occupation is dodging the hailstorm of juvenile literature, do not realize that seventy years ago there was practically no children's library of native authorship save the delightful publications of Peter Parley (S. G. Goodrich), also a Connecticut man. We remember well how eagerly we fell upon Mr. Gallaudet's charming

little "Child's Book of the Soul," and the series of scripture biographies and writings for the home, school, and church which during these years came from his pen as from an overflowing fountain of wisdom and love. The American Tract Society alone printed and circulated 600,000 copies of these admirable publications, and they were translated into all the leading European languages and read by thousands of old and young around the world. Among his writings of great educational value was the widely read essay, "Public Schools a Public Blessing."

But, like many other distinguished friends of the common school, he never found one where he would educate his own five children, all of whom were trained in a model school in his own house, with a few companions, where he had them in constant oversight. His services as lecturer and official in public and private seminaries, with constant calls to the pulpit and annual addresses, were a profession in themselves. He spent several months in a laborious visit through the West and Southwest, on an evangelical mission among the German people of those States. He was the president of the Hartford Missionary Association, and all his life greatly interested in the work of the Colonization Society for the Free Negroes, one of the benevolent dreams of that far-off time. During the last years of his life he served as the chaplain of the Retreat for the Insane at Hartford and displayed wonderful aptitude in reaching and controlling the unfortunate inmates of this asylum. In 1838, at the age of 49, he was urged to accept the office of secretary of the new Connecticut State board of education, Henry Barnard, then in the legislature, offering to assist in making up a salary sufficient for his support. Earlier than this he was the first choice for the presidency of the first State normal school established in the country, at Lexington, Mass.

But in the delicate state of health in which he remained for the last twenty years of his life, he was doubtless wise in his avoidance of professional or public position. Thereby he became a sort of universal father and adviser of all the prominent educators of the land, and, more than any one man, was sought out and held in wide esteem as an authority in pedagogics and the wisest friend of the teachers and children. He was always a devout believer in the substance of the old-time Evangelical religious creed, as modified by the enlarged interpretation of men of great spiritual genius, like Dr. Horace Bushnell, and always a preacher of the religion of everyday living. His moral scruples even extended to the avoiding of political action, and his only vote was cast, at the age of 61, for President of the United States. "He was the best beloved of all men; a true son of the light." As the director for the Hartford Retreat for the Insane wrote, "When he died, sunshine went out of the house." In the language of another, "He possessed the rare genius in pedagogy in making even children themselves feel that education is a priceless thing."

Dr. Gallaudet died in 1850, worn out with labors that might task the energies of many strong men, at the age of 63, in Hartford. But he had lived long enough, like his great friend, Dr. Barnard, to see all that he had projected, and more than he had ever dared to hope, become the common possession of the whole country, both in his specialty of the training of the deaf and dumb and, generally, in the eminent success of that revival of popular education of which he was one of the chief apostles.

He received collegiate honors from an institution of learning in a State that was a wilderness when he was born—the Ohio Western Reserve College; and his final home in Hartford was made possible by an appropriation of money from the board of directors of the institution from which he had found it greatly for his comfort to retire twenty years before. It is from such men and women, as from deep reservoirs of wisdom, love, and beauty that the great educators of every generation refresh their failing stores of inspiration and power, and go forth "with strength renewed, like the eagles," "to fight the good fight" for the children and "keep the faith" in education as the soul of the nation's life.

HENRY BARNARD IN WISCONSIN.

The period between January, 1855, when Dr. Barnard resigned his second school superintendency of Connecticut, and June, 1859, when he assumed the position of chancellor of the University and agent of the board of normal regents of the State of Wisconsin, was by no means barren of results to this indefatigable educator. He had revisited Europe, and for him a visit anywhere was an occasion for careful observation. The American Journal of Education was begun, and a score of valuable articles, each a treatise, had been prepared for its pages. But three more essays at a life of executive activity were to be made before he could give himself fully to the great labor of his last thirty-five years, even yet prolonged; the brief and energetic episode of his presidency of the University of Wisconsin from June 1, 1859, to January 1, 1861; the even more brief and less eventful assumption of the presidency of St. John's College, Maryland, in 1866; and his final work, as first Commissioner of the national Bureau of Education, from 1867 to 1870. Our present interest is chiefly concerned with the first of these terms of educational supervision.

The early history of the common school in Wisconsin has elsewhere been told, and it only remains to glance at the condition of popular education in this new State in 1858 in order to frame the familiar figure of the man who by this time had richly earned the title "The national educator." Among the frequent educational visits of Dr. Barnard, ranging from Charleston, S. C., to the new Northwest, perhaps the most fruitful was his appearance at Madison, Wis., at the invitation of Hon. John H. Tweedy, in 1846, to present the subject of popular education to the constitutional convention of the Territory. At a meeting called for that purpose, Dr. Barnard outlined a scheme for public education which, reduced to writing, was practically accepted and incorporated in the constitution then submitted to the people. It included local taxation in connection with the distribution of the State school fund; a general superintendency of education, and the establishment of a State university, with a normal school department. This constitution was rejected by the people. But in 1848 the same provisions became a portion of the new scheme as a permanent article of the fundamental law. The subsequent legislation under the constitutional provision was largely drawn from Michigan, the first Northwestern State that had at once put on the ground an effective and complete system of public education without the violent struggle and long delays that hindered the effort in Ohio, Indiana, and Illinois.

In 1851 the State of Wisconsin was admitted to the Union, with a population of 305,391. The State was indebted to Mr. Root, afterwards first State superintendent of common schools, for the present wording of the educational clause, and he seems to have been largely influenced by a graduate of the Albany, N. Y., normal school, a pupil of Principal Page, who was then a teacher in the Territory. The common-school ship was bravely launched with only one-half the children of school age (4 to 20) on board, at the moderate expenditure of $76,000. But in the stimulating air of the new Northwest all good things grow apace. In nine years the large sum, for a new State forty years ago, of more than $1,000,000 had been expended for the common schools, more than one-fourth the entire revenue of the State. A series of active superintendents—Root, Ladd, Wright, and Barry—had urged on the State to grapple with the situation. For nine years in succession a new recruited army of children, 25,000, appeared each year at the schoolhouse door.

In 1858 Wisconsin nominally stood at the head of the common-school States in the proportional number of children of school age. Her school fund, derived from the national gift of public lands, was already $3,000,000, with a prophecy of $5,000,000 in a not distant future. There were already a score of free high schools established in as many of the larger towns. Milwaukee boasted a schoolhouse

costing $28,000. The university had already been founded, but was hardly yet in vital touch with the people, its whole number of students not exceeding 100, with a smaller number in actual collegiate studies. The department of instruction under Professor Reid scarcely numbered a score of young men.

The administration of Hon. Lyman C. Draper, in 1858–59, as represented in his voluminous and vigorous reports as State superintendent of education, seems to have marked a new era. These documents, like many subsequent reports from the State and local superintendents of education in the Northwest, are elaborate treatises on the public school question, with long quotations from the foremost educators of our own and other countries, important declarations of celebrated statesmen, pages of interesting correspondence conducted by the school authorities of the State, and eloquent appeals to the laudable pride and ambition of new Commonwealths in constant peril of being absorbed in the exasperating conflicts of partisan politics and the material development of a new country. Among other topics the great importance of the superior training of teachers is discussed at length. After an intermittent debate of six years, the legislature of 1857 had passed a law for the establishment of a normal school fund from the income of an extensive region of swamp lands—a misleading name for a vast area containing much valuable real estate. The yearly income was to be divided among such colleges, academies, and high schools as were willing to submit themselves to an examination and partial supervision by a board of State normal regents. The law also provided for a normal department in the university, and a small appropriation was made for a professorship of pedagogy as an annex to another chair of instruction.

But even then the enormous work of launching a new American State as extensive, at that date, as each of a dozen European kingdoms, was only begun. Superintendent Draper declares that nearly 100,000 children and youth, one-third of the entire school population from 4 to 20, were in no school. This was not so poor a record as it may seem, since an overwhelming majority of the children in the Union even now leave school before the age of 14, and in a new Territory, thronged by recent immigration, the labor of boys and girls between 12 and 20 would be an important consideration. Of 244,000 children and youth of school age, 167,000 were enrolled in the common schools, with 90,000 outside. In the the same year Ohio, Michigan, and Indiana reported but one-half, Illinois one-fourth, and Massachusetts and New York three-fourths of their school enumeration in attendance. But it is probable that in New York and Massachusetts the school age was shorter at both ends. In 1857 there were, in round numbers, in Wisconsin 4,000 school districts and 3,480 schoolhouses, one-third built of logs, and a school property of $1,127,000. Male teachers received $27 and females $15 per month; 1,375 school libraries contained 38,000 volumes. In nine years after its admission to the Union as a State Wisconsin had expended $2,000,000 upon its public schools, one-fourth of the entire public expenditure of the Commonwealth. The annual income of the school fund of $3,000,000 was $200,000, 75 cents for each person of school age in the State. Training for teachers had been well secured by a provision that one-fourth of the income of the public swamp lands should be a perpetual fund for this purpose. Teachers' institutes had been established and several institutions of learning had availed themselves of the appropriation for normal instruction.

It was under these flattering conditions that Dr. Henry Barnard was called from his laborious literary retirement to renewed activity, this time in the supervision of the higher and normal departments of education. Each of these in Wisconsin was under a separate organization and both were a portion of the public school system. His previous appearance in the State, with the added experience of twelve years in Rhode Island and Connecticut, had aroused the highest expec-

tations. Superintendent Draper devotes a generous space in his report of 1857 to an account of the public career of the great educator, and heralds his coming in the following eloquent words: "As a promoter of the cause of education, the career of Dr. Barnard has no precedent and no parallel. We have reason to felicitate ourselves on the acquirement of such a man. It ought to form a new era in our State history, and it will if we are true to ourselves and true to him. We shall best favor ourselves and bless the State by listening confidingly to and carrying into effect whatever suggestions and advice such a man as Henry Barnard, with his ripe experience and noble devotion to the good of his race, may deem it his duty to offer on matters pertaining to the great cause of popular education in Wisconsin." Certainly, with a public school term of but five and one-half months, 1,000 children in one all-out-doors county unable to attend school for lack of proper clothing, and only two-thirds of the school population, all in need of instruction, inside even a log schoolhouse, the coming of this man of national reputation, "trailing clouds of glory" from his abundant success in the far-off East, was an apparition to awaken the most extravagant demonstrations of an excited frontier expectation.

Dr. Barnard was called to the chancellorship of the university and the agency of the board of regents of the normal-school fund in 1857. His coming had also been announced by State Superintendent Barry as "the most important event in our educational history, if not, indeed, the most important, in view of its public consequences, that has ever transpired in the history of the State." His specific duties as agent of the normal board of regents was "to visit and exercise a supervising control over the normal departments of all such institutions as shall apply for a participation in the normal school fund, to conduct teachers' institutes and normal instruction in the same, and to cooperate with the superintendent of public instruction in procuring a series of public educational addresses to be delivered in the various parts of the State." It was even declared that "the State was passed over, as it were, into Dr. Barnard's hands."

It was a very difficult and, on its face, a vastly greater opportunity than the call of Horace Mann at an earlier date to the presidency of Antioch College, Ohio; financially bankrupt from the start and environed by a thorny wilderness of sectarian, provincial, and personal jealousies. But the very extravagance of the great expectation and the pathetic confidence of the educational public of an entire Commonwealth in Dr. Barnard's case was, in itself, the chief peril of the situation. The school affairs of the State were in the condition of a lusty youth every year "outgrowing his clothes" and plunging into life under the combined supervision of two "governors," each looking somewhat askance at the other and both a good deal at sea concerning the proper management and the probable cost and outcome of training their precious charge. The two bodies of regents and the common school authorities, represented by the State superintendent of instruction, were getting into action without strictly defined definition of their respective duties. And it was several years before the present university and normal school system were finally established on a foundation as nearly ideal as may be expected in an American Commonwealth, the university supported by an ample tax on all the property of the State, and the five normal schools and teachers' institutes provided for by a permanent fund of $1,000,000.

The actual coming of Dr. Barnard was delayed till June 1, 1859. But, as usual, he began the work with the tremendous impetus of the great sweeping machine that does the work of a small brigade of men wielding the old-time street brush-broom. It is recorded that the new chancellor, contrary to the practice of the regulation college president of the day, confined his labors in the university to his proper sphere of supervision—the laboring oar being still worked by the faithful Professor Sargent, practically the continuous "dean of the faculty," through the most trying early period of the institution—and gave little time to instruction.

But there was an ample and more urgent field for his peculiar genius in the organization of the difficult normal enterprise that had been undertaken by the State. At once he took the agencies on the ground in hand and worked in good faith, whatever may have been his private judgment concerning the system in operation. He introduced a series of oral and written examinations of the normal classes in the colleges, academies, and high schools. In this he did all that could be done to lift the discarded New York system of subsidizing irresponsible private seminaries for training the teachers of the public schools. The effort was doubtless somewhat beneficial, although it only amounted to a compromise with the public obligation of establishing a system of State normal schools. This work was delayed by the oncoming and outbreak of the civil war. The normal department of the State University, under the pedagogic superintendence of Professors Reid and Charles A. Allen, never became an element of considerable importance. Perhaps its best result was in opening the doors of the university to women, for the large majority of the normal students were of that sex.

Another excellent service was the republication of four of the educational documents that were now appearing from the indefatigable pen of Dr. Barnard. Of these papers treating of the organization, instruction, and discipline of common schools 1,000 copies were sold among the teachers of the State.

But Dr. Barnard gave his most effective service in Wisconsin through the institutes for teachers. He was the true father of this national normal school on wheels, and up to this period no man had it so well in hand. During the autumn following his advent in the State he had organized and conducted with marked success a series of institutes in twenty counties, that reached three-fourths of the teachers in Wisconsin. Several prominent educators were called in as workers in this field, in which Dr. Barnard was himself the most inspiring of leaders. Several of these gentlemen remained in prominent positions in the State. In his last report Superintendent Draper writes "the gratifying success which has attended the teachers' institutes under the direction of Chancellor Barnard, held during the past autumn, should be regarded as among the most hopeful signs of the times." "First and foremost is the great work of providing a better education for the masses of the people, and like Saul, the son of Kish, a head and shoulders above his fellows, is Henry Barnard. He comes to us ripe in educational experience, and is devoting with unflagging energy the best years of his life to the honor and glory of Wisconsin. In the marked success which has attended the series of teachers' institutes held at various points in the State during the past autumn we have the strongest assurance of the future. Our normal schools, our teachers' institutes, and teachers' associations, these all-important agencies in elevating the character of the free schools, will all feel the genial influence of his persuasive instruction and the marvelous power of his zeal, his talents, and his genius. With such a leader all should be proud to follow, and for such an educator, all untiring as he is in devising plans for the achievement of a yet higher standard of intellectual improvement, we should all—legislators, school officials, teachers, and people—feel it always a privilege and a duty to strengthen his hands and encourage his efforts."

There is no evidence that the educational public or the people of Wisconsin were disappointed in their expectations of the value of the services of their new citizen educator. But the time of his coming was not auspicious for the cause of education. Already were the clouds thickening along the horizon that prognosticated the breaking of the awful tempest of the civil war. Wisconsin was among the most radical and earnest even of the Western States in its policy of resistance to what it regarded the aggressions of the slave power, and in its legislation concerning the return of fugitive slaves had practically thrown down the gage of battle. During the short eighteen months of Dr. Barnard's residence in the State—June, 1859, to January, 1861—the public mind was like a troubled sea, and not even a pilot as enthusiastic and confident of himself as Dr. Barnard could

have steered in safety through the raging billows. And it had already been demonstrated that he was not by temperament or physical constitution in his own highest place in the post of school administration. Even in Rhode Island and Connecticut, excellent as were the results of his labors, it is not improbable that his greatest influence was through the wide circulation of his written documents that were "flying on the wings of the wind" all over the country and even across the ocean, with his frequent visits to different portions of the United States, where he appeared like an inspiration, and left everybody more assured of the good cause. And not the least notable of his qualities was that "persuasive faculty of instruction," the genial temperament which De Quincey declares the evidence of all true genius, which amid the dogged conservatism of the old Connecticut and Rhode Island East and the perilous enthusiasms of the new, progressive West, left him always the same, impervious to public approbation or neglect, ever intent on the main object in view.

Such a man is always weighted with a double burden, the inflexible will and tireless industry to do the work at hand and the even more exhausting mental occupation of watching the issues of all movements as they bear on the general outcome of the nation's life. It was this, a man carrying a whole country on his shoulders along with the active administration of the most vital interests of one community, which eventually broke down the oversensitive physical constitution of Dr. Barnard. This time the collapse came even while his followers admired and published abroad his untiring energy of labor. In 1861 he resigned, again prostrated and in sore need of what he called "entire rest."

In 1860 Superintendent Pickard, the successor of Superintendent Draper, himself one of the ablest and most honored educators of the new West, speaks thus of Dr. Barnard in his first report: "Several volumes of great value to teachers have been prepared and published during the year by Hon. Henry Barnard. They have been meeting with a ready sale, as they certainly deserve. Dr. Barnard has given such an impetus to the cause of common-school education and, through these volumes above alluded to, has furnished such effective helps to the teachers as will cause universal regret at the necessity under which he is laid of seeking the restoration of overtasked and wasted energy by entire absence from the scene of labor. Much has been anticipated from the labors of a man so widely known and so universally respected as Dr. Barnard. Much has already been done. Sickness has checked, but, I trust, not entirely ended his work with us."

It was perhaps fortunate that his retirement was thus forced upon him so early in his career of usefulness in the Northwest. The great civil war was now upon the country and it would have been impossible to have carried on the work of administering the higher educational affairs of such a State as Wisconsin with satisfaction to himself during the coming five years. He had already sounded his own high note of a broad and practical consecration to the cause of the children. And Wisconsin, like all these great Commonwealths, had at home an adequate supply of executive educators who, better than any leader, however famous, from elsewhere, could guide the people through the difficulties of a permanent establishment of public education. Dr. Barnard returned to the work that always stood waiting for him, the editorship of the American Journal of Education, which was but another name for the compilation of the first great educational encyclopedia which, after the test of a generation, remains the noblest collection of material for the study of the growth of every department of educational activity through its development from the origin of the American colonies to the second century of the national life.

The termination of Dr. Barnard's connection with the University of Wisconsin was the proper close of his executive contribution to the great revival of education previous to the outbreak of the civil war. His subsequent temporary presidency of St. John's College, Maryland, and his final services as first Commissioner of the national Bureau of Education, between 1865 and 1870, pertain to a later period.

The American Journal of Education.

But all these labors, now continued for twenty-five years in official life in three States, with a constant habit of visitation, observation, and advice through the Union, were but the overture to the grand opera of the life of Henry Barnard. By native genius, temperament, habits of study, and a wondrous facility of literary production, he was by common consent the chief representative of the literary side of the great educational revival during the thirty years previous to the civil war. Compared with his omnivorous intelligence, the researches and reports of all the educators who visited Europe during this fruitful period pass into eclipse. It was of the first importance that when the attention of the American people was directed, as it has never been but once since, to the national lead of popular education, the leaders of public opinion should not be left to the partial and local results of the experimenting and experience of the first generation of the national life. While everything coming from abroad must be adapted to our own national characteristic ideals and methods of education, it is still of the first importance that the American educational public should be placed in close relation with the great educational theories, systems, and practices of the peoples whose achievements have been the most notable of the civilized world. It was also as important that the different States and sections of our own country, originally separated by obstinate provincial prejudices, should be brought together by a fair comparison of the best that had been done in every State and section. Here was a field so interesting that it is not remarkable that a mind so capacious and a spirit so catholic as Henry Barnard should, early in his career, have planned a lifework to meet this imperative demand.

As early as the beginning of his educational career, in Connecticut in 1838, this idea had possession of him. The Connecticut Journal of Education was only a rehearsal of the great educational library and encyclopedia now known as the thirty-one volumes of the Henry Barnard American Journal of Education. The same idea runs through it. While containing a great deal of valuable matter adapted to the condition of the schools in Connecticut, every number was ballasted by a solid treatise, often in the form of a report in some direction, that was an exhaustive treatment of an important theme. At the close of his first term of secretaryship in Connecticut, in 1842, his great plan of a history of education in the United States seems to have been clearly before his mind, and he commenced the preparation of documents containing the results of his studies, reenforced by his valuable experience of superintendency. The call to Rhode Island suspended the proper development of his plan; but it was partially carried out in the publication of the Rhode Island Journal of Education, which was the continuation of the method of editing already seen in the Connecticut Journal. During his second term of service in Connecticut the aid of the legislature was granted to the publication of a series of papers of great value, including the history of school legislation in that State.

The materials were already at hand for a proper beginning of his long-contemplated work. In December, 1854, Dr. Barnard presented to the American Association for the Advancement of Education, held in the Smithsonian Institution in Washington, a broad "plan of a central agency for the advancement of education in the United States." It was received with favor by the association and a committee appointed to carry it into effect "as far as the funds of the association would permit." It is impossible, in reading over the vast project then outlined by Dr. Barnard, to see anything but the original conception of what is now the central American agency, the national Bureau of Education, of which Dr. Barnard was the first commissioner, from 1867 to 1870. Almost every feature of the present Bureau, even the contemplated journal, which is represented by the Bureau's "circulars of information," was there seen in prospect by the great American educator. But there was then neither the funds nor even the disposi-

tion to venture out to sea on a voyage so uncertain by the committee of the association.

Therefore, true to the most characteristic habit of a man of genius—to undertake on his own responsibility what no one else could be persuaded to attempt—Dr. Barnard, in 1855, in connection with Rev. Dr. Peters, who had edited the College Review and Educational Magazine, published in August, 1855, as a literary venture, the first volume of the American Journal of Education and College Review. At the end of the second volume, December, 1856, this arrangement had come to a natural end, and the American Journal of Education was announced by Henry Barnard. To this work he has consecrated his whole life, even to-day lingering around its final arrangements. In the present shape it is a library of thirty-one stout volumes of 800 pages each, 25,000 pages; a proper encyclopedia of education. During the past twenty-five years the international expositions at Vienna and Paris have shown their appreciation of this work by gifts of bronze, silver, and gold medals, responsive to similar acknowledgments at home. The foremost educators of all nations have declared that it is the most valuable collection of educational materials in the literature of any language.

The conception of this great work was worthy of the broad and generous mind of Henry Barnard and could only have been realized by an educator of his peculiar characteristics. The first circular announcement, in 1855, reads as follows: "In the great educational movement now going forward on this continent, and especially throughout all the States in which the English language prevails, there has seemed for many years to the undersigned to exist, if not a demand, at least the want of not only an American association of the friends of universal education, but also of a series of publications which should, on the one hand, embody the mature views and varied experience of wise statesmen, educators, and teachers in perfecting the organization, administration, instruction, and discipline of schools of every grade through a succession of years, under widely varying circumstances of government, society, and religion; and on the other hand, expose real deficiencies, excite to prudent and efficient action, and serve as a medium of free and frequent communication between the friends of education in every portion of these great fields."

The editor also describes it as "a series of publications, including a periodical to be issued monthly or quarterly, devoted exclusively to the history, discussion, and statement of systems, institutions, and methods of education in different countries, with special reference to the condition and wants of our own." And with that wise policy, which is only the law of truth, love, and justice applied to a subject so involved with infinite possibilities of difference and discord as general education, he pledges himself "to studiously avoid the insertion of all topics or papers foreign to the great subject to which it is devoted, or of a single line or word calculated to injure intentionally the feelings of any faithful laborer in any portion of the great field of American education."

Such words of healing import must have come like a balm upon the discordant host that the "faithful laborers in the great field of American education" was in 1855. And when we remember that, of all American educators, even not excepting Horace Mann, no writer of first-rate eminence had so bravely stood up for the highest and best, even as an official in his own State had exposed with a severity so relentless the faults, follies, and perils of the prevailing system of public instruction, we can understand what a task this man set before himself and what were the probabilities of success in a plan apparently so visionary.

That it did succeed after a fashion so decisive that the thirty-one volumes of the American Journal and Library of Education for a full half century after its first clear conception by Dr. Barnard remain still unique and unrivaled in any language is the most complete testimony not only to the historical but to the great literary genius of its author. And when to this we add the even more pertinent fact that all this was done with no effective cooperation from the publish-

ing fraternity, even with a scant support from the professional class for whom it was specially compiled, at the financial ruin of one of the most devoted educational apostles of the country and period, our interest and admiration rises to reverence. The practical destruction of such a work, as Robert Herbert Quick wrote, would be equivalent to the "pulling down of one of our cathedrals and selling the stones for building material," and this was averted to some extent by the useful "analytical index," prepared as a guide through the vast and bewildering spaces of this wilderness of precious material. It will be indeed a reflection on the intelligence, not to say the gratitude, of the American educational public if a final editor is not found who can so rearrange and classify this work and bring its historical record of education down to date as to realize the splendid ideal which, like a guiding star, held its devoted author up to long years of research and financial sacrifice through the latter twenty-five years of his life.

Indeed, the neglect of appreciation that compelled Henry Barnard to such toils and sacrifices was but another evidence of the inability even of an educated and patriotic community to compass the aim and end of a scheme so vast or to understand that a man may be defeated on the grandest line of operation for lack of the most ordinary sympathy and material support. Even to-day an enthusiastic and successful teacher of a mission school of 500 children, with a photograph of his building and a club of singers, can collect more money in a week in any great American city than the United States Commissioner of Education in his heroic endeavor to lift up to permanent recognition this greatest literary educational work of the Republic, indorsed by the foremost educators of the world. By a singular fallacy of even the cultivated imagination and philanthropic sentiment, the man who "lives and moves and has his being" in the capacious realm of far-reaching and universal plans is supposed to have at his command the resources of the whole country for its prosecution. But the venerable author of this noble work may yet have to add the final wreath to his "crown of rejoicing" that not only has every position, ideal, and plan of his general scheme of popular education become the commonplace of the American common school, but his own world picture of education in all its departments has been accepted and esteemed as it deserves.

The plan of Dr. Barnard in this publication was like the dream of Lord Bacon in the Organon—to take all education for his province. The work gives in sufficient measure and detail for the practical understanding and use of the general reading public of the United States a fair history of education from the earliest ages to the present time. Its account of the great modern revival of the educational spirit and methods, under the leadership of central Europe, from Comenius to Froebel, is ample for general understanding and use. Its résumé of educational history and recent activity in Great Britain lays a solid foundation for the just comprehension of the Colonial and early national history of our American common school. Its elaborate illustrations of the new education—academic, collegiate, scientific, and industrial—in our own country is so intelligent that even the humblest inquirer can read. A careful examination of this great work by a competent reader will explain the fact that every essential feature and the most effectual methods of our present common school life have been outlined, suggested, and elaborated in their present form during the educational career of its author.

The complaint of the class of critics who find only confusion and evidence of careless, unskillful, and crude editorship in this great encyclopedia is rather a criticism of their own lack of appreciation of his situation and of the environment of his work than of the author. Dr. Barnard did not propose to prepare a universal encyclopedia of education or build a monument of literary enterprise. His large and unique scholarship and catholicity of appreciation for all nations and peoples was shot through and through with an intense and practical patriot-

ism. He declares at the outset his intention to do all this "with special reference to the conditions and wants of our own country."

It was not only excusable but absolutely necessary to condense important works, to present high scientific methods and profound philosophical systems of education in intelligible shape, and generally to adjust, apply, and concentrate the entire wealth of Old World thinking and doing with special reference to this end. Henry Barnard, with all his preoccupation in broad views and prophetic plans, was no builder of educational air castles, but a true son of old Connecticut and the Republic, always working with a clear picture before him of the last little school he had visited or the most destitute or neglected hamlet in the land. In this he was an instructive example for so many ambitious educators who now insist on forcing not only Old World methods of instruction but of administration on our national school life.

The complaint that the information concerning educational affairs in our own country is not classified and wrought into a connected and complete history in this work only reveals the lack of knowledge of the actual condition of educational affairs in our country even to-day, not to say during the period when its materials were collected. In half the Union, through fifteen States, until twenty-five years ago there was no reliable collection of the materials for such a history. The common school as we know it, save in a few cities and in an imperfect condition in two or three States, did not exist until several years after the close of the civil war. The multitude of private schools of every conceivable grade, not to mention the academical and collegiate foundations, have no established habit even of reporting their own conditions, much less of collecting statistics of their own class of seminaries.

The labors of Horace Mann and Henry Barnard may be said to have created the science of educational statistics in the United States. Until the past twenty-five years no serious attempt has been made to write a reliable history of education in any American State, and to-day the attempts at that history in the reports of Mann and Barnard are the best attainable accounts of the common school, even in the two States where it had its birth. It was fortunate that Dr. Barnard in 1842 did not give himself, as he first proposed, to writing a history of American education up to date. His attempt to collect the materials by travel, correspondence, indefatigable labor, and large expenditure of time and money must have early convinced him of the futility of such an undertaking. Until 1860 the National Library at Washington, according to the statement of its present eminent Director, "had never taken in pamphlets;" and in pamphlets and newspapers alone, in many of the States, could be found any considerable record of education during the first two hundred years of the colonial and national life.

In place of this, Dr. Barnard did what could only be done at that time. He gave himself, with the tireless industry and boundless patience that makes every great collector a national "bore," to the collection of every fragment of important information, every memorial of the most ordinary school, every monograph of a valuable institution, every plan of a schoolhouse or public structure for educational or philanthropic use—all statements, probably often misleading and colored by the personal ambitions and narrow outlook of local educators, and plans of operation by any sort of "faithful workers." All this required a largeness of mind and capacity of sympathetic appreciation only possible to an observer of original genius and great practical faculty. Dr. Barnard took information as it came, and gave it as it was, and secured it in its own place in the 25,000 pages of his 31 crowded volumes.

This vast collection of useful and original material, twenty-five years ago, was all that could be called a history of education in the United States. The true historical inquirer, even of to-day, can well appreciate the difficulties that beset Dr. Barnard in such an undertaking, and the priceless value of much that is found in this great treasure house of information. Often in half a page will be

found a clew to the understanding of the educational history of an entire period in the school conditions of a Commonwealth. The popular letters of a New England traveler in Pennsylvania, Illinois, or Tennessee may explain why the common school could not exist there till "the veil was taken away from before the face" of their people. This great work does indeed require the labors of a competent editor, working not in the interest of any pet theory or with a foregone determination to reconstruct any portion of the country or shatter any present reputation, but to condense, collate, and, if possible, put in better shape for the use of the country for which it was intended the vast and rich deposits in this great educational "placer," out of which the fortunes of a succession of pedagogic aspirants have been already realized, and which will remain a "gold-bearing" mine through generations to come.

With this account of the services of Dr. Henry Barnard, up to the year 1860, on the edge of the black cloud that was surging up from the horizon to herald the terrible five coming years, not even rolled by in 1870, the opening period of the second great revival of the American common school, we close this biographical sketch of the lives of the two great leaders in New England of the movement that revolutionized and reconstructed the original common-school system of the country. Here the common school was, from the first, a literary institution, under charge and in contact with the literary class. Its most influential administrators were clergymen and teachers; even the majority of the most distinguished public men of this section had at one time been teachers. Hence in New England the revival of the common school came up from and was held fast in the hands of the leading educational class, and the educational public was but another name for the educated people. The theological agreement among the Congregational churches which represented the only original American ecclesiastical polity and the homogeneity of the New England population kept the common school for the time outside the disastrous conflicts of creeds. What we now call "the religious question" was not a disturbing element, although the schools were greatly affected by the intense religious life of the time. Here and among the great body of those who swarmed from the old New England hive into the region beyond the Hudson River, we notice a great interest in the pursuit of education as a science. Horace Mann and Henry Barnard and the group of able school men and women that gathered around them became the foremost representatives of the great revival of the common school, and their powerful influence was felt through the entire country during the thirty years from 1830 to 1860.

We have presented these great leaders of the progressive American educational public at this period because it was only in New England that such a crisis could have appeared at the close of the first half century of the nation's life. And only in the two States of Massachusetts and Connecticut, where the American common school had its birth, where through the one hundred and fifty years of the colonial period it was the real popular university, and where it was near to the people's heart, might such leaders be expected to appear. From the first the common school in New England was in charge of the educated class. The Congregational clergy was still the leading educational body and the leader of the professional class up to 1830, and this was the most effective agency by which the State and the towns administered the public will in every department of education.

When we come to the great Middle States, the scene changes. The division of the people in their cosmopolitan civilization, owing to diversity of nationality, sect, and social caste, so involved the clergy and the teaching profession that the complete establishment of the common school was finally an upward movement from the people, engineered by and for many years virtually under the direction of the most progressive statesmen and the secular professional class. Hawley and Wadsworth and Seward, Dr. Franklin, Dr. Rush, and Thaddeus Stevens, Bishops Doane and Potter, the famous secretaries of state in New York—Spencer, Dix, and Young; Daniel D. Barnard and the Randalls and the group of eminent

public men like Van Rensselaer, and many of the eminent lawyers and merchants of the metropolis were, until a late period, the leaders of popular education. Even during the revival period, beginning in 1830, with the exception of Dwight and Page, no large number of prominent educators appeared to follow the steps of Dr. Eliphalet Nott and Mrs. Emma Willard.

The new "Great West," then hardly including the five Northwestern States east of the Mississippi, even until the civil war, owed the upbuilding of the higher grades of their educational systems largely to the labors of men who were profoundly interested in the public-school movement. Their leading college and academical presidents and professors were largely imported from the East and were so devoted to the denominational seminaries and colleges that the people were left a good deal to their more intelligent politicians and progressive men of affairs for the final establishment of the common school.

The Southern States, though including half the number of Commonwealths and more than half the settled area of the Republic, had little part in this general movement for the revival of the common school, outside the border and a few cities of the Southern Atlantic and Gulf States. Owing to the increasing agitation of the slavery question, it is doubtful if the negroes enjoyed the opportunity of the occasional instruction of their more capable class as in former years. The great mass of the nonslaveholding white people, with the usual exceptions of youth of marked natural superiority in ability and energy, were still left to the meager supply of the "field" and private schools and whatever satisfaction could be gained from the free-school system of several States; generally so poor that the people most in need had practically "no use for it." Three of these States had made a more decided and persistent effort to adopt the free common school for its white population—Missouri, Kentucky, and North Carolina.

But the revival of which we now treat was not inoperative through this extended region. The most thoughtful educational and public men of these States were greatly aroused and inspired, especially by the eloquent writings of Mann, Barnard, and others only second in rank. The visits of Henry Barnard to the South, especially in New Orleans, La., and Charleston, S. C., were influential in the establishment of the common school for white children in several of these cities. Horace Mann was also consulted in regard to the establishment of the first public schools in New Orleans, and sent there his friend, Mr. Shaw, whose name is still cherished in that city. The only United States Commissioner of Education from the South, Hon. N. H. R. Dawson, informed the writer of this essay that his own interest in the public-school system was awakened and educated by the correspondence of his father with Horace Mann.

But the South did not need to sit at the feet of the Northern section of the Union for instruction and encouragement in this direction. Indeed, the growing political hostility was probably to the prejudice of the common school as one of the most prominent features of Northern civilization. It was only necessary to look backward to Thomas Jefferson and the illustrious group of the fathers who, even before the establishment of the Union, joined hands with the North in the most important educational legislation of the century, the consecration of one thirty-sixth of the entire area of the national land patrimony to the education of the youth of all succeeding States, even at the sacrifice of their own imperative necessities, to look forward with longing eyes to the appearance of the new time coming. Many of the most striking appeals in behalf of public education in our national literature came up from these States to cheer and inspire the great workers in the North. No greater boon could now be offered to the South than the publication of a series of these documents, messages of governors, reports of legislative committees, the proceedings of educational conventions, and written addresses by eminent educators, in popular form for general distribution among the Southern people.

CHAPTER XVII.

REPORT OF THE COMMITTEE OF TWELVE ON RURAL SCHOOLS,

APPOINTED AT THE MEETING OF THE NATIONAL EDUCATIONAL ASSOCIATION JULY 9, 1895.[1]

To the National Council of Education.

The undersigned Committee of Twelve on Rural Schools, appointed at the meeting of the National Council of Education, Denver, Colo., July 9, 1895, has the honor to submit the following report discussing the rural school problem in its four several aspects, each of which has been the special care of a subcommittee of three persons, who have submitted their results from time to time to the criticism of the entire committee. These subcommittee reports are preceded by a general introduction, written by the chairman of the Committee of Twelve, in which a history of the formation of the committee is given, together with a brief summary of the recommendations of the several subcommittees. In the appendix[2] will be found a number of valuable contributions illustrative of different points made in the several reports.

REPORT OF THE COMMITTEE ON RURAL SCHOOLS.

INTRODUCTION.

To the National Council of Education:

The undersigned, chairman of the Committee on Rural Schools, appointed at the meeting of the National Council of Education, Denver, Colo., July 9, 1895, would respectfully submit the following report:

At the meeting of the council on July 5 the Committee on State School Systems

[1] Reprinted from the edition published by order of the board of directors (Chicago: The University of Chicago Press, 1897).

[2] The appendices, to which frequent reference is made throughout the report, have not been reprinted. A list of them is given at the close of the chapter.

made a report on the rural school problem, through its chairman, Henry Sabin. C. C. Rounds, president of the council, urged immediate action, in view of the importance of the subject and of the growing interest in the question of improving the condition of the rural schools. Other members joined in the discussion, and, on motion of B. A. Hinsdale, the chair was directed to appoint a committee of five, who should submit a plan for the further investigation of this subject.

July 9 the committee reported as follows:

Resolved, That there be undertaken, under the auspices of the council, an investigation of the subject of rural schools, embracing such topics as revenues and expenditures, the constitution, organization, and duties of boards of management and control, and the provision of suitable teachers. More definitely, said investigation shall be conducted in general on the lines laid down in the report of the Committee on State School Systems submitted to the council at its present session.

Resolved, That a committee of nine be appointed to conduct this investigation, said committee to consist of the following persons: Henry Sabin, of Iowa; D. L. Kiehle, of Minnesota; A. B. Poland, of New Jersey; C. C. Rounds, of New Hampshire; J. H. Phillips, of Alabama; B. A. Hinsdale, of Michigan; S. T. Black, of California; W. S. Sutton, of Texas, and L. E. Wolfe, of Missouri.

Resolved, That the board of directors of the National Educational Association be urgently requested to appropriate, at some session to be held during the course of the present annual meeting, the sum of $2,500, or such part thereof as may be necessary, to defray the expenses of this investigation, including the publication of the report of the committee.

Resolved, That the committee should report within the period of two years, in such form as it may determine, and that it be authorized to publish its report.

Respectfully submitted.

B. A. HINSDALE,
G. P. BROWN,
D. L. KIEHLE,
J. R. PRESTON,
EARL BARNES,
Committee.

At the same time the committee was empowered to enlarge its number to twelve, and to fill any vacancies which might occur.

On the 12th day of July the directors adopted a series of resolutions, under which a sum not exceeding $2,500 was set aside and placed in the emergency fund for the use of the committee. The resolutions also provided that not more than $1,500 should be drawn during the year 1895-96; that no compensation should be allowed any member of the committee, and that the fund may be drawn upon, if necessary, to defray in whole or in part the publication of the report. It is proper to add here that at a meeting of the directors at Buffalo, upon the request of the council, an additional $1,000 was placed in this fund for the use of the committee under the same conditions as above.

The committee held its first meeting July 10, 1895, at which time, on motion of Dr. Hinsdale, the committee was increased from nine to twelve by adding the following persons: W. T. Harris, Washington, D. C.; L. B. Evans, Augusta, Ga.; C. R. Skinner, Albany, N. Y.

Messrs. Sabin, Kiehle, and Hinsdale were constituted a special committee to formulate a plan of work and furnish members with copies of the same; also to divide the committee into sections and to assign appropriate work to each.

The committee as finally constituted consisted of the following gentlemen:

Henry Sabin, Des Moines, Iowa, chairman; B. A. Hinsdale, Ann Arbor, Mich.; D. L. Kiehle, Minneapolis, Minn.; W. T. Harris, Washington, D. C.; A. B. Poland, Trenton, N. J.; C. C. Rounds, Plymouth, N. H.; J. H. Phillips, Birmingham, Ala.; S. T. Black, Sacramento, Cal.; W. S. Sutton, Houston, Tex.; C. R. Skinner, Albany, N. Y.; L. B. Evans, Augusta, Ga.; L. E. Wolfe, Kansas City, Mo.

The special committee of three met in Chicago October 25 and 26, 1895, and, after consultation, divided the entire committee into four subcommittees, and assigned certain topics to each for investigation and report. These subcommittees

were constituted and the work assigned to each in accordance with the following schedules:

I. *School maintenance.*—Subcommittee: B. A. Hinsdale, chairman; W. S. Sutton, S. T. Black.

This branch of the subject was divided for convenience into three subheads:

1. *Revenues.*—Permanent school funds; taxation, general and local, embracing State, county, township, and district taxes; miscellaneous sources of school income, such as fines, licenses, gifts, etc.

2. *Expenditures.*—Machinery and methods of distribution, general and local. The main points to be considered are the channels through which the funds reach the schools and the rules and methods governing their distribution and application.

3. *Organization of business administrative machinery.*—The county, district, and township unit systems; the consolidation of schools; the transportation of pupils; county, township, and district high schools; the relation of rural schools to city schools. Inquiry should be made into the main social, industrial, and economical factors that condition rural education, as density of population, wealth, means of communication, etc.

II. *Supervision.*—Subcommittee: L. B. Evans, chairman; C. R. Skinner, Henry Sabin.

1. The manner of electing the superintendent, State, county, district, or township.

2. Minimum qualifications required of each, and term of office.

3. The relation of the superintendent, State, county, district, or township, to the teachers and pupils as officer and adviser.

4. The relation of the superintendent, State, county, district, or township, to school officers, and their duties.

5. The relation of the State superintendent to the county and township superintendent.

6. The relation of the superintendent to the public at large, as creating and shaping public opinion in rural districts.

7. The relation of the superintendent to school buildings, architecture, sanitation, and hygienic conditions.

III. *Supply of teachers.*—Subcommittee: C. C. Rounds, chairman; J. H. Phillips, D. L. Kiehle.

1. An inquiry into the assistance rendered rural schools by the following facilities for preparation:

(*a*) Normal schools.

(*b*) Training schools in high schools and academies.

(*c*) Summer training schools.

(*d*) Institutes.

2. An inquiry into the means provided for the improvement of teachers already in the service:

(*a*) Teachers' meetings and associations.

(*b*) Reading circles.

(*c*) Libraries and current literature.

3. An inquiry into the manner of electing, employing, and paying teachers:

(*a*) By what authority examined and certificated.

(*b*) By what authority employed.

(*c*) Terms of engagement, certificates, and salaries paid.

IV. *Instruction and discipline.*—Subcommittee: W. T. Harris, chairman; A. B. Poland, L. E. Wolfe.

1. Methods of teaching and government peculiarly affecting rural schools.

2. Courses of study, text-books, and other appliances.

3. Working programmes.

4. Gradation and classification of pupils.

5. The relations of rural schools to their environments; as to farm life, mining life, etc.

It was also provided that the investigation of the several subdivisions of the general subject should follow two main lines:

1. The condition of rural schools now existing.
2. Changes to be recommended; what is, and what should be.

It was not thought necessary that the committee should go into history or development further than to make the conditions that now exist, and the reforms that are recommended, intelligible. It was also recommended that changes to be made, or reforms to be proposed, should have respect to existing facts; that they should be practical in the rational sense of that word.

It was further left to the several subcommittees to determine the methods to be employed in carrying on their work, and to exercise the greatest freedom in enlisting aid from every possible source.

Each subcommittee was thus left free to formulate such questions as seemed best designed to elicit the desired information in the most definite form.

The committee met at Jacksonville, Fla., February 18 and 19, 1896, for consultation and comparison of results. An informal meeting was held during the sessions of the National Educational Association at Buffalo in July, 1896, at which time it was determined to hold a meeting of the full committee at Chicago, November 18 to 21, 1896. The chairman of each subcommittee was also directed to have such preliminary matter ready at that time as would embrace all the essential points necessary to a fair understanding of the scope of the final report to be made to the council in July. It was also voted to ask certain experts in rural school matters to meet with the committee, in order that it might have the benefit of their experience.

The committee met at the Auditorium in Chicago, as determined. The entire committee was present at each session, with the exception of D. L. Kiehle, who, for satisfactory reasons, was not present until Thursday morning. The following gentlemen were present upon invitation of the chairman:

John MacDonald, editor of the Western School Journal, Topeka, Kans.; W. W. Stetson, State superintendent of Maine; J. L. Pickard, of Iowa City, Iowa; O. T. Bright, county superintendent of Cook County, Ill.; Albert G. Lane, city superintendent of Chicago; D. E. McClure, county superintendent of Oceana County, Mich.; W. H. Chandler, of Madison, Wis.; President F. W. Parker, of the Chicago Normal School; G. R. Shawhan, county superintendent of Champaign County, Ill.; John Trainer, of Decatur, Ill.; T. C. Chamberlin, of the University of Chicago; J. J. Schobinger, of Morgan Park, Ill.; W. S. Jackman, of the Chicago Normal School; A. W. Edson, State agent, Boston, Mass.

Wednesday and Thursday were devoted to general discussion, one-half day being allotted to each of the four subcommittees in the following order: School maintenance, supervision, supply of teachers, and instruction and discipline. Friday and Saturday were devoted to the consideration of the preliminary reports submitted by the chairmen of the respective subcommittees. The sessions were held from 9 a. m. to 12 m. and from 3 to 6 p. m. In order to facilitate discussion printed or typewritten copies of the main propositions in each report were placed in the hands of those present. During Friday and Saturday the reports were read section by section, and, after alterations and amendments as suggested by various members of the committee, they were adopted.

It was further ordered that the reports of the different subcommittees should appear in the printed volume in the following order:

1. School maintenance.
2. Supervision.
3. Supply of teachers.
4. Instruction and discipline.

On motion the entire matter of printing the report, when completed, was intrusted to the charge of the chairman of the committee, with the suggestion that he confer with the United States Commissioner of Education in regard to securing the cooperation of the national bureau for publication purposes.

T. C. Chamberlin, of the University of Chicago; W. S. Jackman, of the Chicago Normal School, and F. H. King, of Madison, Wis., were requested to prepare a discussion of the possibilities of a course of study especially adapted to agricultural environments. This discussion constitutes Appendix G of this report.

Appendix A, consisting of a paper read by B. A. Hinsdale before the department of superintendence at Jacksonville, is published by order of the committee. The course of study for rural schools and the paper by Dr. White, designated as Appendix I, and the paper by F. W. Parker, Appendix H, are inserted by the same authority. The other matter in the appendix has been placed there in accordance with a vote of the committee, leaving the selection to the choice of the chairman of each subcommittee and of the general committee.

The date for publication of the report was fixed at from four to six weeks before the meeting of the National Educational Council at Milwaukee. After determining that the chairman of each subcommittee should send a typewritten or printed copy of his report to each member of the committee before publication for suggestions or amendments, the committee adjourned.

In the foregoing historical statement no attempt has been made to follow the exact order of proceedings, but only to gather from the secretary's records such main points as will give the council exact information of the methods adopted by the committee.

As soon as possible after the adjournment of the committee the chairman of each subcommittee prepared his report, and printed or typewritten copies were sent to other members, and also in all cases to persons who were supposed to be able to point out omissions or to suggest alterations. As a result these reports represent the combined experience of many competent persons besides members of the committee. This method led to much correspondence on the part of the chairmen, but it has undoubtedly aided them very materially in making a broader and much more comprehensive report. The committee found itself confronted from the beginning with the fact that the environments of schools differ so much in various sections of the country that it is impossible to make other than very general suggestions. Conditions vary so much between Maine and California, or Minnesota and Texas, that what would be an excellent system in one would possibly fail in the other.

SCHOOL MAINTENANCE.

Those who read the following reports will find that several recommendations are made by more than one subcommittee. Thus in the matter of organization the necessity of adopting a larger unit than the district, as the township or the county, is very strenuously insisted upon by two or more subcommittees. It is a fact of such great importance that other essential points hinge upon this. The arguments are very fully stated in the report of the subcommittee on school maintenance, but the general committee is fully agreed upon the desirability of effecting this change wherever the district system at present prevails. It would conduce to effectiveness and simplicity of organization; to economy in the use and distribution of funds; to the equalization of the burdens of taxation, and to a system of supervision which would produce better results from the instruction given in the rural schools.

Again, all the subcommittees are strongly in favor of the consolidation of schools which are too small to employ profitably the time of one teacher into larger schools, when practicable, in order that better instruction may be provided than is possible under the present system. This involves also paying for the transpor-

tation of pupils to some central school at the public expense. The different subcommittees have reached this conclusion, each from its own standpoint. The inferences drawn from facts and figures are too obvious to need any argument. The conclusions arrived at in the discussion of the two points, organization and consolidation, are very broad, and would seem to be applicable to some section of nearly every State in the Union.

The manner of raising and distributing the revenues has been carefully investigated, and the subcommittee having that subject in charge seems to have reached very wise and just conclusions. The township or special district in which the parents of the pupils reside should contribute to the school funds, as should the county and the State. Every interest concerned in the education of children should bear a proportionate share of the burden of taxation. In the distribution of school funds, because of the community of interests involved in popular education, the strong and wealthy must contribute to the support of schools in weak and impoverished districts. It may not be possible to provide equal school facilities in every part of the State, but every district in which a school is established should be assured beyond all doubt of a sufficient sum of money to employ a competent teacher for the minimum number of months or days fixed by the law. The duty of providing for the pupils of the rural schools the means whereby they can have the benefit of high schools in their neighborhood has not been overlooked. It is not necessary to discuss fully these points. Attention is invited to them, as set forth in the report of the subcommittee on school maintenance.

SUPERVISION.

The subject of school supervision is discussed under the general divisions of State, county, township, and district. The task assigned this subcommittee is difficult, because, as far as rural schools are concerned, there are no well-defined lines of work upon which there is a general agreement. There is great need of supervision which is intelligent and which carries with it some degree of authority. As a general thing, the officer known as State superintendent has only advisory authority. He can make suggestions, but they carry with them no more force than there is in the character and influence of the officer who makes them. He is too far removed from the rural schools, and is too much engaged in other matters connected with his office, to come into close touch with them and their present interests.

No one questions that supervision should be compulsory. In fact, such is the case in most States to-day. The great question connected with it is how to make it effective. A supervisor who has charge of a hundred schools or more, scattered over an entire county, finds it impossible to control and direct them in accordance with well-devised plans. Accordingly the subcommittee urges township or district supervision where it is practicable, or that each supervisor should have such deputies or assistants as will enable him to reach every part of his field.

Again, if supervision is to be effective it must be the product of skill and intelligence. As well put an ordinary seaman, selected from the crew by lot, in charge of an ocean steamer, with its precious cargo of lives and wealth, as to place a raw, uncultivated man or woman, selected by the chances of a political convention, in charge of the schools in which our youth are being trained for citizenship. The subcommittee is of the opinion that certain qualifications, moral and mental, with some experience in teaching, should be exacted from everyone who aspires to the duties of a supervisory office. The duties which are incumbent upon a supervisor of schools have been so minutely discussed that it is not necessary to restate them here. It is sufficient to say that knowledge and skill, enthusiasm and patience, sympathy and forbearance, firmness and justice, are requisite in one who would discharge his duties conscientiously and with due regard to the highest good of all concerned.

The importance of bringing the school into touch with the farm and the home has been dwelt upon at some length. (Appendix O.) To this end the supervisor should make himself thoroughly acquainted with peculiar conditions of life in his supervisory district. It is not enough that he visit the school and consult with the teacher. He must meet school officers and parents, awaken their sympathy and arouse their interest, if he would do his whole duty. He must have a controlling influence in the selection of teachers, in the erection of school buildings, especially as concerns sanitation and hygiene, in teachers' meetings, and in general school work throughout his entire territory.

A wise supervisor can not fail to observe carefully the environments of the school, which exert a powerful, though unconscious, influence upon the character of the pupils. The bearings of the æsthetical upon the ethical side of the child's nature, the relations of music and art as determining the development of the child along right lines, should be observed and guarded as well in the rural as in the city schools.

SUPPLY OF TEACHERS.

The question of the support afforded teachers is one great hindrance in the way of improving the rural school. The following table, showing the average monthly salaries paid teachers in rural schools, has been compiled from answers to circulars sent out to State superintendents. It is unfortunate that in most States the statistics make no distinction between city and rural school teachers. Consequently many of the returns are estimated. They are valuable, however, for purposes of comparison and general information.

States.	Males.	Females.	States.	Males.	Females.
Alabama	$25	$20	Missouri	$40	$31
Arkansas	33	30	Montana	60	45
California *a*	67	56	Nebraska	35	30
Colorado *b*	50	45	Nevada	85	60
Connecticut	30	30	New Hampshire	30	30
Delaware	35	33	New York *d*	37	37
Illinois	30	25	Ohio	35	30
Indiana	40	35	Pennsylvania *e*	42	33
Iowa	35	30	Rhode Island	40	36
Kansas	40	32	South Carolina	30	27
Kentucky	36	34	South Dakota	36	31
Louisiana	40	33	Utah	53	37
Maine	35	22	Vermont	39	27
Maryland	29	29	Virginia	28	25
Massachusetts *c*	32	26	West Virginia	36	36
Michigan	29	25	Wisconsin	46	30
Minnesota	40	31	Wyoming	45	40

a Includes schools of not more than two teachers.
b Includes the schools in the agricultural sections only.
c Based on 52 male teachers and 143 female teachers in towns under $500,000 valuation.
d $9.26 a week, counting thirty-three and one-third weeks in a year.
e Not including the city of Philadelphia.

In connection with above table we must take into account that in only a few States is the average length of the school over eight months. This includes cities and towns, as well as rural districts, so that it is fair to conclude that in general the country teacher finds employment not to exceed seven months in a year, and often not more than five or six.

The subcommittee regrets that so few are able to apprehend the qualities essential to a good teacher. Professional fitness is ignored in nearly every case. The smaller the unit of organization the greater is the disposition to engage teachers for short periods of time. All engagements should be for one year at least, and frequent changes of teachers should be discouraged.

Perhaps the most important subject intrusted to this subcommittee has reference to the training and preparation of teachers. There is no doubt that the normal

school in most States does not reach down and take hold of the common district school. There is room, as indicated in the report, for a series of normal training classes with a course of one year, or at most two years, not modeled after a State normal school, but suited in all respects to the needs of a class of young people from whom we draw nearly all our rural school teachers. Instruction for one year in such a school could be made to so inspire students with a desire for knowledge, to so fill them with the teaching spirit, as to work a most beneficent change in the schools coming under their charge.

The proposition to establish continuous sessions in normal schools, as set forth in the subcommittee's report, is full of promise for the improvement of rural school teachers without withdrawing them from active service. The terms and courses could, under the plan, be so adjusted as to enable them to attend a normal school for work in regular courses of study during that large part of the year not occupied in teaching. A course for one year is indicated below. If extended to two years, the extension should consist not so much in the introduction of new branches as in doing something more than elementary work in the branches already in the curriculum.

Course of study for one year of forty weeks.

General divisions.	First term.	Second term.
Language.	Reading and literature.	Grammar. Elements of rhetoric.
Mathematics.	Arithmetic. Algebra.	Geometry.
Natural and physical science.	Geography. Elements of chemistry.	Botany. Elementary physics.
History.	United States history. Civil government.	General history. Biography.
Professional studies.	School economy. Elementary psychology. Practice teaching.	Physiology with special reference to hygienic conditions. Practice teaching.

The number of lessons in each branch per week must be determined by the conditions and necessities of the class. Singing and drawing should have such a place as their importance demands. At least two lessons per week for each of them should be insisted upon.

The course of study to be completed in one year is arranged according to relation of subjects and not according to order of study. It embraces, so far as elements are concerned, those subjects which are necessary in order to enable a teacher to deal with organic and inorganic nature, with history and civil government, with literature and language, and with so much of music and art as the conditions of the school will admit. While provision is made for professional training, the success of such a course as this as a means for preparing teachers for their work will depend almost entirely upon the good judgment and skill of those who are intrusted with the management of the school. The tendency to overload such a course, to crowd two years' work into one, will have to be very carefully guarded against.

The entire course is intended to be only elementary, and is for the benefit of a large class of teachers who have but little preparation, and are not able from various reasons to devote more than one year's time to attendance upon a normal school. The advantages of a school of this nature would be greatly enlarged by the possession of a carefully selected library, and of sufficient apparatus for purposes of illustration and experiment. If the students could be taught to make this apparatus, with maps, charts, etc., for use in rural schools, it would add to their usefulness as teachers. Very great advantage would accrue to the pupils from coming in contact with disciplined minds in the persons of their instructors. But few rural teachers know how to study or how to get the most out of the books which fall into their hands.

Summer schools, reading circles, and institutes have received their share of attention. The whole ground has been well covered and will repay a careful perusal.

The scheme for the examination and certification of teachers has been thoroughly digested. There will be some who may not agree with the subcommittee in all particulars, but no one will dispute the fact that too many teachers in the rural schools are contented with the lowest grade of certificate which will answer the purpose of the law. There is a great necessity for some scheme such as is here recommended, whereby teachers can rise step by step in their calling, if they earnestly desire to improve. On the other hand, this scheme furnishes a reasonable excuse for not affording further professional recognition of any kind to those who show no disposition or no ability to do anything better in the line of preparation for their work.

INSTRUCTION AND DISCIPLINE.

The report under this head will be found to embrace several important recommendations. Some of these will provoke discussion, but most of them are of such a nature as to commend themselves to every thoughtful person. The report opens a broad field of inquiry, which must of necessity receive more attention as the wants and necessities of rural schools are better considered.

The evils of attempting to grade the rural school as the city school is graded are very clearly set forth, accompanied by the suggestion that those normal schools which as part of their work train teachers for rural schools should carefully impress upon such teachers the necessity of considering the size of the school in determining the uses and abuses of grading and classifying pupils. This suggestion is all the more pertinent in view of the movement in many States to require some previous professional training as a prerequisite for entering any public school as a teacher.

Considering that the course of study for the rural school need not differ in any material point from that provided for the city school, it is urged that the aim of such a course is to enable the pupil to recognize the conditions of inorganic and organic nature, and to pursue the studies of literature, language, and history, as they are necessary for his entrance upon civilization. The difference in courses of study for rural or city schools is found to be in those collateral branches which relate to the environment of the pupil or to the neighborhood in which he dwells. The report upon this point is very full and will repay a careful study of its details. The subcommittee calls especial attention to the relation of the course of study to the system of grading and classification. The suggestions made are of great practical value in any discussion which endeavors to determine the method of adapting a course of study to the wants and conditions of rural schools. It can not but be very helpful to be told that the course of study is the measuring rod used only to determine at what point in his work the pupil has arrived, and not a Procrustean bed used to give the work the lifeless beauty of a dead uniformity.

The consolidation of those schools which have become so reduced in numbers as to render it unprofitable to maintain them separately, the transportation of pupils at public expense to other schools than their own, and the concentration of higher-grade pupils at a central point, are urged as means of lessening many of the evils from which rural schools are suffering. This provision, having been grafted into the law of several States, bids fair to prove of great benefit. Wherever it has been tried it has commended itself as economical and as a means of affording better teachers and consequently better schools. The matter of improved roads enters incidentally into this discussion, as having great bearing upon the question of transporting children to central points for school purposes.

In connection with school exercises at the town or county center once or twice a year, competitive examinations are not recommended unless they are very care-

fully guarded. The feature of social intercourse, the stimulus which comes from meeting with his mates, have advantages which ought not to be overlooked or neglected.

Home reading, with what is termed school extension, is dwelt upon at such length as its prominence demands (Appendix O). To carry good reading material, whether of science, literature, or fiction, prose or poetry, into the schools and homes of the rural districts must be a part of any educational scheme which has for its object making country life more endurable or more attractive. The various recommendations of this part of the report are worthy of careful consideration at the hands of those even who may not wholly agree with them.

CONCLUSION.

Your committee has called in the aid of a number of persons whose time and thought have been largely given to matters connected with the management and instruction best suited to the wants of rural schools. It was found impossible to embrace the entire matter placed at our disposal in the body of the report. We have, therefore, printed much of it in the form of an appendix, believing that it will add largely to the value of this report. It is not to be supposed that every point has been covered, or that the entire subject has been exhausted. The committee has endeavored diligently and to the best of its ability to throw some light upon what may possibly be regarded as a collection of subjects embracing a very large field. While there are many points worthy of especial attention, I have gathered up the following as a brief summary of those which may be considered of most pressing importance:

SUMMARY.

1. For purposes of organization, maintenance, or supervision, nothing should be recognized as the unit smaller than the township or the county; the school district is the most undesirable unit possible.

2. Every community should be required to raise a certain sum for the support of its schools as a prerequisite for receiving its share of public money. A certain definite sum should be appropriated to each school out of the State funds, and the remainder should be divided in accordance with some fixed and established rule, a discrimination being made in favor of townships most willing to tax themselves for school purposes.

3. One of the great hindrances to the improvement of the rural school lies in its isolation, and its inability to furnish to the pupil that stimulative influence which comes from contact with others of his own age and advancement. The committee, therefore, recommends collecting pupils from small schools into larger and paying from the public funds for their transportation, believing that in this way better teachers can be provided, more rational methods of instruction adopted, and at the same time the expense of the schools can be materially lessened.

4. There is a tendency to fill the rural schools with untrained, immature teachers. The establishment of normal training schools, under competent instructors, with short courses, each year of which shall be complete in itself, would do much to remedy this evil. The extension and adjustment of the courses and terms of the State normal schools so as to constitute a continuous session would enable them to contribute more directly than now to the improvement of the teachers of rural schools (Appendix S). The State would then be justified in demanding some degree of professional training from every teacher in the rural as well as in the city schools.

5. The establishment of libraries, the prosecution of the work of school extension by lectures and other means, the introduction of such studies as will have a tendency to connect the school and the home, especially those having a direct bearing upon the everyday life of the community, and the necessity of applying the laws of sanitation to the construction of rural schoolhouses demand immediate attention.

6. The rural schools are suffering from the want of official and intelligent supervision. In every State some standard of qualifications, moral and intellectual with some amount of actual experience, should be demanded by law from those who aspire to fill the office of superintendent or supervisor of schools.

7. Good morals and good manners constitute an essential part of an educational equipment. The inculcation of patriotism, of respect for law and order, of whatever tends to make a good citizen, is of as much importance in a small as in a larger school. Regularity, punctuality, obedience, industry, self-control, are as necessary in the country as in the city school. Country school teachers should call to their aid the beautiful things in nature, that with reverential spirit they may lead the children to reverence Him who hath made all things good in their season.

HENRY SABIN, *Chairman.*

REPORT OF SUBCOMMITTEE ON SCHOOL MAINTENANCE.

The maintenance of an efficient State system of public instruction involves numerous sociological factors of an important character. This is particularly true in a democratic State, where public opinion gives the final sanction to all public activities. Moreover, there is good reason to think that it is even more important to consider such factors carefully when providing rural schools than when providing urban schools. The bearing of the wealth of the State, both in the aggregate and in relation to population; the density of population and the ratio of rural to urban population; the ratio of the adult or wealth-producing population to the population of legal school age; the facilities for travel and the character of the people in respect to race elements—the value of such factors as these in the problem is almost too plain for argument. (Appendix A.)

The organization and administration of the powers of government must also be considered. The Government of the United States stands to all the members of the Union in the same relation—that is, within the States it has no proper educational function whatever. The State government, however, is a constant factor; it exercises the central State authority. But when we take the next step we are at once confronted by contradiction and confusion.

First, we find in New England the town system of local government. Here nearly all the local governmental functions are performed by the town; the county exists, but it is more a judicial than a political unit, and in Rhode Island it is wholly judicial. The town is much, the county little. Secondly, the county system, which exists throughout the South and in several of the Western States, more than reverses these conditions. The county is the organ of local government, and the township does not commonly exist. The county is divided into districts for the purpose of defining the jurisdiction of justices of the peace, into election precincts, and sometimes into school townships. Here the county is everything, the town nothing. Thirdly, the old Middle States and most of the Western States have what is called the mixed or compromise system. In these States the township is less than in New England and the county more, the county less than in the South and the township more; in other words, both township and county are employed in something like equal measure. Again, two types of the mixed system are found in different States. In New York and the States that have imitated her the county legislative and executive board is composed of supervisors elected by the several townships, while in Pennsylvania and the States that have followed her example this board is composed of commissioners elected by the county at large. The county is, therefore, a governmental organ in all the States, while the township is found only in two groups of States. Moreover, in those States where the town or township is found it varies considerably in powers in comparison with the county. These elementary governmental facts it is necessary to remember, because they directly affect the matter in hand. Manifestly, the people will not be apt to create local organs of government for any one single pur-

pose unless they deem it absolutely necessary. On the other hand, they will manifestly use for any such purpose, as far as consistent, the same organs that they use for other local purposes. This is just as true of schools and education as of other public interests. Except that Vermont has a county examiner of teachers, no mention is made of the county in any New England school law;[1] no mention is made of the town or township in any Southern State, while the States that have the compromise system use both the county and the township as organs for carrying on their schools. It will be seen that no account is here taken of the city or municipality, because this is common to all the States and does not relate to rural schools.

An ambiguity in the use of the term *town* is also to be mentioned. The *township* of the Middle and Western States corresponds in general to the New England *town*, while in these States the *town* is a village, hamlet, or even city. All the recommendations made in this report will recognize distinctly the facts now stated.

Still another preliminary explanation is called for. The term *district* as used in school legislation and in educational discussions is very misleading. The two leading senses of the word must be sharply discriminated. This can be done by describing the two principal forms of local school organization.

1. *The town or township unit system.*—This is something wholly different or separate from the town system of local government described above. The two systems may exist together, but not of necessity so. The town or township unit system, called also the town-district system, is found in connection with both the town and the compromise systems of local government. It could not exist with the county system, as a matter of course. The town system of local government relates to local affairs generally; the town or township district system to schools only. The name township-unit system means only that the town or township is the ultimate unit of school organization and administration. This unit, with such assistance as it receives from the State or county, provides and carries on its own schools independent of any other unit. It raises funds by taxation and expends them, subject only to the law of the State. It is the organized town or township, a body corporate and politic, under its educational aspect. The local authority is sometimes a school committee, as in Massachusetts; sometimes a board of education, as in Ohio, and again a township trustee, as in Indiana. Again, the township-unit system does not necessarily involve the consolidation of rural schools. The school children within the unit may all be brought together in one central school at some advantageous point, or they may attend a plurality of schools scattered through the township. In the second case, the limits or boundaries of the several schools must be marked off for the regulation of school attendance, unless, indeed, pupils are permitted to attend such schools as they please, and these areas are commonly called districts or school districts. In Ohio they are known as subdistricts, and they serve also as units of representation in the township board.[2] Here, then, are two clear uses of the term "district"—one is the town or township, and the other a part of the town or township defined pri-

[1] Vermont, Maine, and New Hampshire once enacted laws creating the county superintendency, but these laws did not remain long on the statute books. No State is likely to use the county for an administrative school purpose unless it uses it for other administrative purposes.

[2] The explanation of the Ohio law on this point is historical. Previous to 1892 the township was the school district proper, but this was divided into subdistricts. The township board of education raised all the local funds by a tax levied on the taxable property of the township and apportioned them among the subdistricts. The subdistrict boards of directors employed the teachers and carried on the schools. The voters of the subdistrict, in annual school meeting, elected the three directors, one every year, for three years, and these again elected one of their number clerk, who represented his subdistrict in the township board. Under the Workman law of 1892 all the old powers of the directors were transferred to the township board, but the subdistrict was left for the regulation of school attendance and to serve as a unit of representation in the township board.

marily for the regulation of school attendance, but also sometimes serving as a unit of representation.

2. *The district system.*—Here "district" is used in quite another sense. Geographically the school district is now commonly a subdivision of a town, as in Connecticut, or of a township, as in Michigan, or of a county, as in the county-system States. Ordinarily it is a body politic and corporate, and is the ultimate unit of school organization and administration. It has its own school committee or board, elected by the voters of the district in school meeting, and, with such help as it receives from the State or county, it builds its own schoolhouse and provides and carries on its own school or schools. It is, therefore, a taxing as well as an administrative unit. Under this system the district is the controlling factor of school organization. Not only is it the most democratic form of school organization, but it has been called "probably the most communistic as well as democratic feature of our political institutions, and is certainly the smallest minor civil division of our system."[1]

Still other districts are mentioned in the laws and reports, as special districts, city districts, borough districts, joint districts, and the like; but these names do not present any new features of an essential character.

These explanations premised, the subcommittee will divide this report into three grand divisions, viz, revenue, distribution, and organization. The last topic, however, will be considered only so far as relates to school maintenance. By school maintenance is meant the provision and support of public schools.

REVENUE.

The subcommittee submits that the first essential to the material improvement of the rural schools of the country is the provision of revenue sufficient for their adequate support. Accordingly this is the first subject to be considered.

The educational items in the budgets of all progressive countries have assumed great proportions and are all the time growing. The Commissioner of Education reports the expenditure for common schools in the States of our Union for the year 1894-95, not including payments on bonds, at $178,215,556. Seven States expended more than $5,000,000 and less than $10,000,000 each, and five more than $10,000,000 and less than $20,000,000 each. New York alone stood above $20,000,000. In 1888-89 the total for the country was $132,129,000, and in 1883-84 only $103,909,528. But unfortunately we have no statistics showing the division of these vast sums between the rural districts and the towns and cities.

A city, in the dictionary of the National Census Office, is a concentration of population containing 8,000 people or more of all ages, and in 1890 there were 443 cities in the country. The Commissioner of Education reports for the year 1893-94 that 3,126,659 children were enrolled in the schools of these cities, to 10,809,318 enrolled in other schools. He reports further that the maintenance of the city schools cost $69,886,413, and of the others $100,497,760. But this is no proper division of rural and urban schools, since the educational conditions existing in many centers of population containing less than 8,000 people are the same as those existing in the 443 cities. At present it costs much more to school 1,000, 10,000, or 100,000 children in the cities than in the country, but this is mainly due to the fact that the education furnished is so much greater in quantity and so much better in quality. It is not improbable that if rural schools were brought as near as possible to the level of urban schools, they would be quite as costly. At least, it is evident that the first condition of good rural schools is a sufficiency of funds with which to provide and maintain them. How shall these funds be provided?

[1] Mr. Wellford Addis, specialist in the Bureau of Education. See Chapter XXXIV of the Report for 1894-95, "The Social Unit in the Public School System of the United States."

I. A century ago the American people began to take an interest in the creation of permanent school funds or endowments. This interest was originally stimulated, if not created, by the policy that Congress foreshadowed in 1785, and subsequently firmly established, to endow the common schools in the public-land States with liberal grants of public lands. In every State in which Congress has exploited the wild lands either one-thirty-sixth or one-eighteenth part of such lands has been dedicated to the public schools. Beginning with Connecticut in 1795, nearly all the nonpublic-land States have also created such endowments out of their own resources. Several of them devoted the United States deposit fund of 1837 to this purpose. At the beginning of the century no one dreamed to what proportions public education would grow in one hundred years; and men thought, not unnaturally, that permanent endowments would greatly ease the burden of taxation for school purposes, and would keep the educational machinery of the State constantly running and well regulated. It will not be denied that, relatively, these funds have come far short of meeting the expectations of those who laid their foundations. There can be little doubt that in many of the States, and particularly when such States were new and poor, they have hastened educational development; but it is quite certain that they have often done great harm, causing the people to rely upon the feeble income derived from them, and to turn their faces away from the only adequate source of school maintenance—that is, public taxation.

Texas has been gazetted as having the most magnificent possibilities of any State in the way of a permanent school fund, but some citizens of that State are now questioning whether these possibilities may not prove other than an unmixed blessing (Appendix B). The fact is, public schools in the United States have far outgrown all present or prospective endowments. In 1888–89 the income from such funds was $9,825,000 in a total of $132,125,111; in 1894–95 the corresponding figures were $8,336,612 and $177,597,691; that is, the per cent fell from 7.4 to 4.7 in six years. New York and Ohio derive less than $300,000 each of their great school revenues from permanent funds, and Pennsylvania derives nothing from such a source. In fact, it would require a permanent fund of $400,000,000 to carry on, at the present scale of expenditure, the common schools of either New York or Pennsylvania. The subcommittee submits, therefore, that all permanent school funds, either State or local, should be carefully husbanded and wisely administered; that they should be preserved intact, and the income be scrupulously applied to the support of schools; that, under special conditions, it may be wise to augment old funds or create new ones, as when certain miscellaneous revenues can be devoted to that purpose; but that such funds must necessarily play a constantly diminishing part in popular education. Massachusetts is committed to the policy of adding to her fund $100,000 a year, raised by taxation, until a total of $5,000,000 shall be reached, and New Jersey to the policy of similarly dedicating the proceeds of certain riparian rights that belong to the State; and to this there is no objection; but for these States, or any others, to lean heavily upon such funds for school maintenance would be a most fatuous policy. Public education is, or at least should be, a recognized function or service of the State. The public schools of the country are civil schools, created and carried on by the civic authority, and they must rest ultimately upon the same general means of support as the other functions or services of government. As well, therefore, endow any other branch or function of the State government, such as the asylums and hospitals, the judiciary, the civil service, or the militia, as the State schools.

II. Gifts to popular education should be sedulously encouraged. Education has long been a favorite object with public benefactors, as the annals of every progressive country show, and none more convincingly than our own. No doubt when the public mind is aroused to the advantages of popular education, and school taxes are abundant, such persons who choose an educational object for their

beneficence will rather be inclined to seek some other form or kind of education. Still the constitution or laws of nearly every State, if not indeed every one, provide for the acceptance and use of private gifts for school purposes, and there are generous persons who are peculiarly interested in the common schools. Scattered over the country are many local public-school endowments that had a private origin, and such gifts have not come to an end.

The subcommittee is not aware that there are any statistics showing how far private benevolence contributes to public education, but it is apprised that the contribution is by no means contemptible, and it believes that it might be made considerably larger than it is. The favorite forms of such contributions under existing conditions are most likely to be land for building sites and apparatus and libraries for schools, and the subcommittee is of the firm opinion that much more could be done than at present in all these directions, and particularly in the way of procuring apparatus and books for the schools in communities where the public funds that are available for these purposes are meager or insufficient.

III. The great resource of the public school is, and must continue to be, some form or forms of public taxation. The ratio of the total school revenues derived from taxes to those derived from permanent funds is all the time growing, and it will continue to grow. At two periods, separated by six years, the sources of the common-school revenues expressed in per cents were as follows:

Year.	Taxes.	Permanent funds.	Other sources.
1888–89	85.9	7.4	6.7
1894–95	85.7	4.7	9.6

Manifestly such areas or units of taxation should be created, or continued if already in existence, as will fully develop the sound American principle that the whole wealth of the State shall be made available for educating all the youth of the State. This is both right and necessary, for it must be remembered that in the United States education is a civil or State function to be supported like other similar functions. What shall these units of taxation be? The subcommittee names those following as coming under the principle just stated:

1. *The State.*—A liberal provision of funds from the State treasury, to be distributed according to some rational method, is indispensable, as a rule, to the maintenance of a good system of State schools. Formerly the burden was mainly or wholly thrown upon the local units. The old Massachusetts plan was to throw upon the towns the whole burden of maintaining their own schools. But the greatly increased cost of schools, growing out of enhanced salaries, longer terms, and improved material equipment, long ago demonstrated that this plan must be materially modified. Many local taxing units are too poor to carry such a load and they must either abandon all hope of good schools or they must receive assistance from the State or social whole. The fact began to gain recognition as early as the middle of the century.

When the constitution of Ohio, adopted in 1851, provided that the legislature should make such provisions, by taxation or otherwise, as, with the interest arising from the permanent school fund, would secure a thorough and efficient system of common schools throughout the State, the law-making power hastened to levy upon all the property of the State, as rated by the assessors, a State school tax of 2 mills on the dollar, to be distributed on the basis of the school enumeration. Taking the country together, the cost of public education is divided between two or more taxing units. Still the fact remains that the part which falls to the local unit is often disproportionate. In 1888–89 the per cent of the total amount of school revenues raised by local taxation was 66.8 to 19.1 per cent raised by State taxation. In 1894–95 the corresponding per cents were 67 and 18.7. The ratio of

the two elements is variable in different divisions of the Union and in different States of the same division. The per cents raised by State tax, as reported, range all the way from zero to a maximum of 83.2, found in North Carolina. We should naturally expect the Southern States, since local government is there less fully developed than at the North, to rely relatively much less on local taxation and much more on State taxation, and such is the fact. But political habit is not the only factor that enters into the problem; economical conditions also assert themselves In a State where wealth abounds and is somewhat evenly distributed throughout its limits, as where manufacturing and commercial towns are frequent, there is not the same necessity for the State, as a unit, to assume a large proportion of the whole burden that there is in a State where wealth is meager, and where such wealth as exists is largely found in a few concentrations of population, leaving large areas thinly populated and poor. These remarks will throw light on the per cents of school moneys raised by State taxation and local taxation in the five divisions of States that the Census Office recognizes. The date is 1894–95. (See also Appendix B.) No account is here taken of income from other sources than taxation.

Division.	State taxes.	Local taxes.
	Per ct.	*Per ct.*
North Atlantic States	19.4	68.2
South Atlantic States	38.1	51.3
South Central States	48.4	31.7
North Central States	9.9	75.4
Western Division	23	61.3

In some of the States, as will be shown hereafter, local taxation must be more fully developed than in the past or present; in others, and these principal States, too, the same may be said of State taxation.

2. In all States where, for other local purposes, the county is the sole unit of taxation, a liberal county tax should be levied for the schools. This proposition applies especially to those States where the county system of local government prevails In States where, for such purposes, the county is a large unit of taxation, it may be wise to levy a county school tax: that circumstances must determine. This remark applies to the States having the mixed system of local government. Under the town system county taxation for schools would be out of harmony with the social and political traditions of the people, and could be accomplished only through a change of habit; perhaps this end is attainable. For the year 1894–95 the Commissioner of Education shows that 67 per cent of the total school revenues of the country came from local taxes. The scale ran from 1.7 per cent in North Carolina to 98.2 in Massachusetts. Unfortunately we have no statistics showing from what sources the local taxes come; how much from districts, towns, and counties, respectively. The point must, however, be strongly pressed that local supply for public education should be forthcoming, as well as State supply. It is a great mistake to teach the people to look altogether, or mainly, to the State treasury for school maintenance. They should rather be taught to depend in due measure upon themselves. It is the confident opinion of the subcommittee that some States are now committing this mistake. Many States having the county system of local government have in the counties a resource for school maintenance upon which they have never adequately drawn.

3. In those States where the town or township is a large taxing unit for other local purposes it should also be made to contribute liberally to public education. This recommendation it would be idle to urge in most of the Southern and in some of the Western States, because the civil town or township does not exist, and it would be vain to urge its creation for school purposes exclusively. But in

those States where the town and mixed systems of local government exist a township school tax would be congruous with the general social and political habits of the people. The desirability of local taxation for school purposes was urged under the last head. Such taxation develops self-reliance and local character, and tends to awaken and keep alive the interest of the people in the schools. The town was the sole school taxing unit in old New England, and it is still a prominent, sometimes almost an exclusive, one throughout the Northern States. The local school taxes of New England are town and district taxes, and taken together they range from the minimum of 69.2 per cent of the whole in Maine to 98.3 in Massachusetts. It can hardly be doubted that the New England States, as well as some others, now throw the burden too heavily upon the towns and districts, and that they will find it advantageous considerably to raise the ratio which State taxation bears to local taxation. The other New England States will probably follow, sooner or later, the example of Maine, which raises nearly one-third of her school money by State taxation. In some States, no doubt, the townships should carry a heavier weight than at present, at least as compared with districts. At all events, the township should bear a reasonable part of the cost of its own education.

4. Special districts, as incorporated villages, towns, and cities, the subcommittee considers not only proper but necessary units of school taxation. Such districts are the concentrations, large or small, of population and wealth; they are the industrial and social centers of the country. We have already seen that in 1893–94 $69,886,413 was expended for school purposes in the 443 cities of the Union. In Massachusetts $7,088,000 was expended in cities; in New York, $12,723,000; in Pennsylvania, $7,745,000; in Ohio, $5,097,000; in Illinois, $8,110,000. If we had the figures for the smaller cities and the incorporated towns, the aggregate would be much increased. Now, not only do the cities, taken together, raise by taxation nearly all of the school money that is expended in them, but, as will be shown in another place, many of them contribute largely to the support of rural schools. Again, they must in the future, collectively as before, contribute still more largely to this end. Special districts, then, are essential as taxing units, care being taken to secure approximately a fair distribution of the public burdens. As a rule, dwellers in cities are much better able to pay heavy taxes than dwellers in the country, but there is great reason to fear that they do not always do so.

The school district, in the commonly accepted sense of that term, is not a desirable taxing unit, but the contrary. It is now such a unit in a majority of States, and the subcommittee is decidedly of the opinion that it should either be made much less prominent than it is or be abolished altogether. As a rule, the second course is to be preferred (except in special districts already mentioned). The town or township is the smallest area that should be employed for this purpose. Even this may be overweighted, as can easily be shown. The unanswerable objections to district taxation are the inequality in burdens that results, and the inability of many districts to carry the load that good schools would necessarily impose upon them. A few statistics will make both propositions perfectly clear.

In 1871 Superintendent Fallows, of Wisconsin, published a table showing the amount of property assessed per scholar in the school districts of a certain township, which he believed to be a type of the state of things generally existing throughout that State. The maximum was $2,860; the minimum, $784; the average, $1,378.

In 1878 Superintendent Graham, of the same State, published a table for the whole State, showing that the valuation of property per district varied from $2,300 to $1,979,708. Districts with less than $3,000 and districts with $40,000 were found in the same township. But the poor districts were required by law to maintain a school six months in the year, just as the rich ones were. The ratio of district taxation ranged from half a mill to 55 mills on the dollar. Superintendent Wells,

of Wisconsin, published similar facts in 1893 for a number of States. He showed that in Rhode Island some districts were taxed fourteen times as heavily as others, and in Connecticut a similar disproportion existed. In New York the ratio of tax raised in two counties varied from 0.0012 per cent in one district to 0.0431 in another. One township presented the extremes, 0.0009 and 0.0070, and still another one 0.0048 and 0.0371. Two districts in one township paid respectively $5.66 and $58.11 per capita; two in another one, $5.43 and $60.37; two in a third, $11.25 and $181.85. "That is to say," says Mr. Wells, "the rate of taxation is seven times as great in one district as in another in the same town, and the per capita cost of educating a child is eleven times as great."[1] But the first of these New York comparisons presents a ratio of almost 40 to 1.

Statistics such as these could be collected almost without limit. The most instructive way to study the subject is, so to speak, on the ground. If a man unfamiliar with it, who lives under the independent district system, will only take the trouble to collect the facts relating to his own county he may easily be astonished at the result. And yet, as a rule, the law lays upon the districts, rich and poor alike, the same burdens in respect to school maintenance. It is hard to see how or why the people have so long borne such inequalities—inequalities so contrary to the cherished American principle that the property of the State should educate the youth of the State; or, rather, it would be hard to see why they have borne them if we did not know the extent of the public ignorance on the subject and the strength of conservative habit, and did not see also how the district as a taxing unit is bound up in men's minds with the district as a unit of administration. But the two are not inseparable. The legislature of Ohio abolished the district as a taxing unit twenty-five years or more before it abolished the district as an administrative unit. In Connecticut, too, town taxes and district management are both met with in the same towns.

Before dismissing units of school taxation, a single point calls for closer attention. This is raised by the question, What is the advantage of looking to large units for supply rather than small ones?

The answer to this question rests upon the fundamental assumption that public education is a State function, and that the whole State is responsible for the education of all the youth of the State. Now, if the cost of public education bore the same ratio to the ability of the people to bear this cost in all the communities of the State, or, what is nearly the same thing, if the wealth per capita of all the communities were equal, then, as a matter of course, it would make no difference whether the school tax were levied upon large areas or small ones. But this is far from being the case. The cities are indeed concentrations of both absolute population and school population, as well as of wealth; but their wealth tends to increase much more rapidly than either the absolute or the school population. The fortunes of the country are either made in the cities or else tend to flow into the cities. The last report of the Census Office shows the per capita wealth of the Union, of the States severally, and of the five groups of States, but it does not show the per capita wealth of the cities and of the rural districts separately. The nearest approach to it is the tables showing the per capita value of real estate with improvements, by States and counties. These averages throw important light upon the subject, and some examples will be given.

Illinois: State average, $860.88; highest county average, $1,311.90; lowest county average, $164.64.

Massachusetts: State average, $848.01; highest county average, $1,564.10; lowest county average, $466.65.

New York: State average, $969.66; highest county average, $1,733.35; lowest county average, $305.80.

[1] "Township System of School Government." Madison, Wis., 1894.

Ohio: State average, $689.01; highest county average, $1,562.56; lowest county average, $265.99.

Pennsylvania: State average, $719.13; highest county average, $1,049.88; lowest county average, $187.26.

If personal property were included, the extremes per capita would be still more widely separated than they are at present. Formal argument is not needed to show that the rich counties are much more able to contribute to the expense of government, education included, than the poor ones, and the proposition that a due proportion of such expense should be thrown upon these units rests upon this fact. The tendency would be to remove inequalities in bearing the common burden. Levying the local school tax upon the township instead of the districts that compose it, or upon the county instead of the townships, would work in this direction. It is very true that townships are unequal in per capita wealth as well as districts, and counties as well as townships; still the fact remains that large units are less unequal than small ones. Every step toward the highest taxing unit tends to distribute the burden more equally. In fact, the argument for removing a portion of the burden from the small taxing units to the large ones is the same that justifies us in calling upon society to educate individuals or families that are too poor to provide for their own education. Why do we impose a public tax for educational purposes at all? Simply because education is a common interest, while some individuals or families are unable to educate themselves.

It may be said that the line of reasoning which has been followed would lead to placing the whole burden of State education at the door of the State treasury. Why should not the State defray the cost of the common schools, just as it defrays the cost of the reform schools for boys and girls, and of the asylums and hospitals? It must be confessed that this would be strict logic. However, we are to remember that governments are never carried on according to strict logic, and can not be from the very nature of the case. What is more, there are the best of reasons, as shown above, for making education, to a reasonable degree, a local charge—reasons that do not apply to some other public services. The people are more likely to be vitally interested in the schools if a portion of their cost is derived from local taxes. In no country of the world, so far as the subcommittee is aware, is elementary education made an exclusive general charge. It is not desirable that it should be. The present contention is for a reasonable distribution among the several taxing units. At the same time, it may be worth observing that in some countries there is a strong tendency, as in England and France, to rely more than formerly upon general rather than local supply.

The appropriations for schools that States make from the common treasury differ greatly in form as well as in amount. Massachusetts levies no State school tax, but the legislature nevertheless votes various specific appropriations, as for the salaries and expenses of State agents, aid to pupils of normal schools, compensation of local superintendents, the payment of high-school tuition for pupils living in towns whose valuation of property does not exceed $500,000 and that do not maintain a high school. Connecticut raises annually a State school tax equal in amount to $1.50 multiplied by the number of persons in the State between the ages of 4 and 16, as enumerated annually. Rhode Island, while not levying a State school tax, so called, votes enough money out of the State treasury each year to make, with the income of the permanent fund, a total of $120,000. New York raises annually, by taxation based on the real and personal property of the State, such sum for the support of schools as the legislature shall determine. New Jersey assesses and collects a total State tax amounting to $5 for each person in the State between the ages of 5 and 18 years. It is this tax that places New Jersey at the head of the column of Northern States in respect to the per cent of school revenue derived from a State tax. The constitution of Pennsylvania provides that

the State legislature shall appropriate every year $1,000,000 from the State treasury for the use of schools, but the present appropriation is $5,500,000.

Ohio levies a tax of 1 mill on the dollar of the grand tax duplicate of the State. Indiana raises 11 cents and Kentucky 22 cents on each $100 of taxable property. The Michigan law directs the supervisor of every township to levy a school tax of 1 mill on the dollar for schools within the township, but as the proceeds are kept within the districts where they are raised, this is only a compulsory local tax; still it stimulates further local taxation for the grand object. The legislature of Michigan also levies a specific tax on certain corporations, as railroads, etc., which is first applied to the payment of interest on the various educational funds that the State has borrowed, as the university, agricultural college, and common-school funds, and then to the support of the common schools. Nebraska makes an annual levy and assessment not exceeding 1½ mills on each dollar's valuation on the grand list of taxable property. The California system of school finance will be mentioned under distribution and in an appendix. These are a few of the States; still others will be dealt with in connection with distribution.

The basis of school taxation, or the ultimate sources of school supply, is an important subject. Whether more money can be had for the schools often depends upon the manner in which it is proposed to levy the tax. In general, taxation for schools will conform more or less closely to the character of the State taxing system as a whole. While admitting the great importance of the subject, the subcommittee does not feel called upon to discuss beyond offering brief remarks on two or three points.

Pennsylvania meets her annual State school appropriation, in whole or part, by laying a tax of 4 mills on the dollar on all moneys loaned by citizens of the State. Some States levy poll taxes, and some "occupation" taxes, for their schools. Quite miscellaneous sources of school revenue are met with in the State constitutions and laws. We find specific taxes on dogs, and on banks, railroads, and other corporations. Escheats and forfeitures are often, or commonly, devoted to the schools. The constitution of Nebraska prescribes that all fines, penalties, and licenses arising under the general laws of the State shall belong and be paid over to the counties where such fines, etc., may be levied or imposed; also that all fines, penalties, and licenses arising under the rules, by-laws, or ordinances of cities, villages, towns, precincts, or other municipal divisions less than a county shall be paid over to the same, respectively; and further, that all these moneys shall be appropriated exclusively to the use and support of common schools in the respective divisions where the same may accrue. Nor is Nebraska peculiar in so dedicating such funds. It has been suggested to the subcommittee that an inheritance tax would prove a popular as well as an abundant source of school supply.

DISTRIBUTION.

The subject of distribution is only less important than that of income. It is easy so to distribute school funds as, first, either to defeat, in whole or part, the very end sought in taxing the larger units for the benefit of the small ones; or secondly, materially to weaken local enterprise and liberality, or wholly to destroy it. The subject will be considered under both these aspects.

1. The assistance that the large political and social units render to the small ones, as the State to counties, townships, and districts; or the county to townships and districts; or the township to districts, should be made contingent, in part at least, upon what the small units do for themselves. No community, it is believed, is so poor that it can not do something toward educating its youth. Again, a State educational system should be so organized and administered as to stimulate, and not repress, local spirit and effort. It is a great mistake to remove the burdens of public education so far from the people that they forget, or tend to forget, their existence. The principle here involved is a vital one. History shows con-

clusively that popular education has flourished most in those States of our Union where government is most democratic.

It is difficult, or rather impossible, to lay down a general rule that shall govern the division of taxation between the State and the local communities. Two things are to be considered. One is the political institutions that exist in the State. If government is largely centralized at State capitals and county seats, that is one thing; if it is largely decentralized, as where the principle of local self-government is fully developed, that is quite another. For example, it would be idle to expect that the same results would obtain in the Southern States that are found in New England, or even in that great group of States where the mixed system of local government prevails. The governmental machinery and the traditions of the people will assert themselves in such matters. The other factors to be considered are social, and particularly economical, conditions. As remarked early in this report, where wealth is abundant and its distribution general and somewhat equal in different communities school burdens may be thrown, and should be thrown, much more heavily upon localities than where the opposite conditions prevail. Density of population, relation of urban to rural population, average wealth per capita, ratio of wealth-producing population to the population of legal school age, the expenditure for education per pupil and per capita, and the per cent of school revenue derived from State taxes and local taxes in the different States, are peculiarly interesting when studied together (Appendix A).

North Carolina shows the largest per cent of State school tax (that is, of the whole tax) of any State in the Union, while the average population per square mile and the average wealth per capita are also small. Maine surpasses all the other New England States in these particulars. The proportionally high ratio of State taxation in the South is due to the two facts stated—political institutions and economical conditions. But there can be no manner of doubt that, as the cities of the South grow, towns multiply, and concentrations of population increase in number and in the value of property, local school taxation will materially increase. Legislatures could hardly prevent it if they should try, and it would be most unwise for them to try to do so.

2. Funds raised by the large taxing units should be distributed in such a manner as to bring the support of the rich and strong to the poor and weak. The only reason for taxing these units at all for general purposes is to secure this end. On no other principle can a State school tax, or even a county or township tax, be defended, unless, indeed, the county or township is a single school district. The practical question is, How shall such funds be distributed so as not to defeat the end in view? A historical account of the leading methods actually pursued will help on the inquiry.

The public-land States may be divided into two classes. From the admission of Ohio to that of Arkansas (1803–1836) Congress gave to the Congressional townships of such States, severally, 640 acres of land each for the perpetual use of schools, and vested the title in the State legislatures. Accordingly in these States every township has its own independent permanent school fund,[1] which is sometimes managed by local authorities and is sometimes in the keeping of the State. Generally speaking, the sum of the township funds makes the so-called State school fund, so far as it is derived from public lands. If the township-unit system prevails, the ultimate distribution of income has been made in advance; if the district system, then the township distributes to the districts. From the admission of Michigan to that of Utah (1837–1895) Congress gave the common-school lands to the States as units rather than to townships, which resulted in the establishment of consolidated State school funds. The annual income from these funds, so far as the subcommittee is informed, is uniformly distributed to the local school

[1] Ohio and possibly other States offer some minor exceptions.

organizations on the basis of the youth of legal school age as enumerated every year. The ages vary, but the principle does not change. It should be added that since the admission of California (1850) 1,280 acres of common-school lands have been given to every Congressional township.

The rule of apportionment just explained is followed far more generally than any other. Thus, Maine distributes her State funds, from whatever source derived, to the towns according to the number of children between the ages of 4 and 21. Connecticut distributes the annual income of her permanent fund and the proceeds of the tax of $1.50 for every child between the ages of 4 and 16 according to the number of children between those ages. Pennsylvania apportions her State tax of $5,500,000 annually, Ohio the proceeds of her 1-mill tax, Michigan so much of her specific tax as goes to schools, and Indiana and Kentucky the proceeds of their State school taxes according to the same general rule.

But other rules are followed. Vermont apportions her State tax to the towns, cities, and unorganized districts according to the number of legal schools maintained during the preceding school year. New Hampshire distributes her State funds to the towns according to the number of pupils returned as attending school not less than two weeks in the year. So much of the Massachusetts permanent fund as goes directly to the schools is apportioned to the towns of the State that have a property valuation of less than $3,000,000, towns ranking above that line receiving nothing. Furthermore, the scale is so adjusted that the poorer the town the larger the amount that it receives. Towns whose valuation does not exceed $500,000 receive $275 each; those exceeding $500,000 and not exceeding $1,000,000 receive $200; those exceeding $1,000,000 and not exceeding $2,000,000, $100, and those above the last amount and not above $3,000,000, $50. Again, a portion of the State fund is divided among the towns that are eligible on the basis of the ratio that the town's school tax bears to the whole town tax; the larger the ratio the more help it receives. Rhode Island distributes her annual State contribution of $120,000 as follows: First, $100 is assigned to every school, not exceeding 15 in number, in a township; then the remainder is distributed to the towns proportionally to the number of children from 5 to 15 years of age inclusive.

The State school moneys of New York are apportioned in a complicated manner. The State superintendent first sets aside the annual salaries of the school commissioners (district superintendents). Next he sets apart to every city, incorporated village having a population of 5,000 and upward, and every union free-school district having a like population, which employ a competent superintendent of schools, $800; and to cities having more than one member of assembly in the State legislature, $500 for each additional member, to be expended according to law for the support of the public schools. He then sets apart any money that may have been appropriated by the legislature for library purposes, and $6,000 for a contingent fund. Next he sets aside to the Indians on reservations, for their schools, a sum equal to their proportion of the State school money, on the basis of distribution established by law. These sums set aside, the remainder of the State moneys is divided into two equal parts. The superintendent now apportions to every district in the State $100 (called a "distributive portion" or "district quota"), provided it has maintained a school, taught by a single qualified teacher or succession of such teachers for the legal term of the preceding school year; and the same sum for every additional qualified teacher or succession of such teachers, not counting monitors. The school year is one hundred and sixty days, not including holidays that occur during the time or Saturdays. This apportionment made, the superintendent divides the remainder of the school moneys among the counties according to their respective population as determined by the last preceding United States census, excluding Indians on reservations. But cities that have special school laws receive their due share separate and apart from the remainder of the counties in which they are situated.

The New Jersey State school tax, equal to $5 for each child in the State between the ages of 5 and 18, is raised by the several counties according to their amounts of taxable property respectively, as shown by the tax rolls of the townships and wards of the counties. Ten per cent of this tax, when it is paid into the treasury, is known as a reserve fund, and is apportioned among the counties by the State board of education "equitably and justly, according to their own discretion." The 90 per cent remaining is then divided among the counties in the proportion that they have contributed to the tax. When the State school moneys reach the counties they, together with all other school funds in the custody of the county, are distributed to the townships and cities on the following basis: (1) $200 for each teacher employed in the public schools for the full term for which the schools are maintained during the year next preceding (nine months); (2) the remainder according to the last published school census (children from 5 to 18 years of age), provided that no district shall receive less than $275, and that districts with 55 children or more shall not receive less than $375. If these funds are not sufficient to maintain a free school nine months in the year, then the inhabitants may raise by a district tax such additional amount as is needed for that purpose.

The local 1-mill tax levied by Minnesota is expended within the districts where it is raised. It is, therefore, only a compulsory district tax, the same as in Michigan. The current school fund of the same State, which includes the income of the permanent fund, is distributed on the basis of the number of pupils who have attended school forty days or more in districts that have had school for five months or more during the year. In addition to the above apportionment, graded schools having not less than three departments, which come up to certain requirements, receive aid from the State to the amount of $200 each. Besides, there are 85 high schools that receive State aid to the amount of $400 each. The grants to these graded schools and high schools are paid from permanent appropriations that are met by general taxation, and are apportioned by the State high-school board, on evidence that the schools are complying with the requirements. Minnesota also gives the sum of $500 annually to State high schools providing elementary normal instruction of a kind that satisfies the high-school board. Wisconsin also has an approved high-school list, one-half the cost of maintaining these schools being paid from the State treasury. Moreover, Wisconsin pays $250 each to certain approved high schools in which manual training is taught.

The California system of school finance is a unique system. The State superintendent apportions to the counties the State school fund according to their respective numbers of school-census children (from 5 to 17, certain classes being excluded). Each county superintendent first ascertains the number of teachers every district in the county is entitled to on the basis of one teacher for every 70 school-census children, or fraction thereof not less than 20, as shown by the next preceding school census, and then the number to which the county is entitled by adding these district numbers together. He then calculates the amount of money to be raised at the legal rate of $500 a teacher. From this amount he deducts the quota of the State fund assigned to the county, and the remainder is the minimum amount of the county school fund to be raised by taxation for the ensuing year, provided that the minimum of such fund shall not be less than $6 for every census child. The county fund thus made up is then distributed to the districts in accordance with this rule, viz, $500 for every teacher, except (1) that to districts having less than 20 census children only $400 is assigned, and (2) that to districts having more than 70 census children $20 additional for every such child less than 20 in number shall be allowed. All school moneys remaining in the treasury after this apportionment has been made are then divided among the districts of the county in proportion to the average daily attendance upon each district during the preceding school year. District taxes may also be raised, subject to certain legal conditions (Appendix C).

The subcommittee does not feel called upon to deal with all the States, or even with all the peculiar modes of distributing school moneys. It believes that the enumeration of particulars now made is ample for the present purpose. Some remarks upon the leading rules or methods of distribution are, however, called for.

1. Distribution according to the school census or enumeration is open to a serious objection, viz, it does not carry the money where it is most needed. For example, two districts lie side by side, one having 20 and the other 40 youths of school age; the second district draws twice as much money as the other, but the cost of keeping up the two schools is practically the same. The same would be true of two township units, unless the schools were consolidated. The result is that the district or township that needs the most help receives the least. The rule is simple and easily worked, but it tends partially to defeat the end of State or county aid.

2. The same objection holds against rules based on the school enrollment or on attendance, only with somewhat diminished force. Again, if the enrollment is followed, or attendance for a brief time, there is danger that some children will go to school long enough to be counted, and then drop out. Besides, such rules of distribution work in favor of the graded schools and against the rural schools, on account of their larger enrollment and more regular attendance.

3. Taking everything into account, the subcommittee is inclined to think that a fixed sum or sums, based on an arbitrary unit or units, is most equitable. Examples of such rules are furnished by the States of Massachusetts, Rhode Island, New York, New Jersey, and California. The most serious objection to such rules is that they are necessarily complicated; some of those given above are quite complicated. Then, if the fixed sum is so much a teacher, as in New York, or so much a district, as in Rhode Island and New Jersey, there is a temptation to the undue multiplication of schools or teachers. But this point can be safeguarded by fixing statutory limitations, as in California. No rule can be devised that will not be open to objection. The subcommittee does not believe it possible to invent any rule of distribution that will well accomplish the purpose of taxing large units for the benefit of small ones, unless it rests on the school or the teacher as a unit with the necessary qualifications. The Massachusetts rule is open to the objection that the school needs of towns can not always be measured by low valuations of property assessed for taxation, as the number of pupils to be educated is also a factor. If the method of distribution now recommended is objected to as an exclusive one, then it may be supplemented by basing a part of the appropriation on the school census, enrollment, or attendance. The resort to the United States census is most objectionable, as great changes of population occur in the course of ten years.

The difference in the working of the school-census method and the fixed-sum method of distribution is well shown by comparing the statistics of two States. For the fiscal year ending November 15, 1895, the mill tax of Ohio produced $1,720,922. Of the 88 counties 40 paid more into the fund than they received from it, while 48 paid less than they received. Some of the major counties of the State received more from the fund than they paid into it, while minor counties paid more than they received. For the year 1896 the city of Cleveland actually received $2,616.67 more from the State than it paid to the State. Assuredly, a rule that makes the agricultural counties of Ohio, or many of them, contribute to the education of Cleveland, the most populous city in the State, is a travesty of common sense.

But the same year Cincinnati paid in round numbers $70,000 more than it received. This is hardly better than repealing the mill tax outright, and letting the burden of education fall directly upon the cities and townships. On the other hand, the State of New York, in 1896, paid a total general school tax of $4,062,903, of which $3,500,000 was immediately distributed to the counties again. Fifty-four of the 60 counties received more from this tax than they contributed to it; only 6

counties paid more than they received. Erie County paid $241,597 and received $185,460; while the corresponding figures for Kings and New York counties were $503,603 and $387,879, and $1,884,584 and $636,133, respectively. The New York rule does bring the strong to the help of the weak.

A question arises in respect to separate funds for buildings, the payment of teachers, and incidental expenses. In the opinion of the subcommittee such division is desirable. The need of providing new buildings is often made an excuse by boards of education for keeping down the salaries of teachers. The triple fund would not indeed prevent such injustice, which makes teachers as such contribute to buildings, but it would tend in that direction. It is often stipulated in school laws that State funds apportioned to communities shall be wholly applied to the payment of teachers. This is a wholesome regulation. The cost of grounds, buildings, and incidental expenses should be met by local taxes or other local funds. Touching the division of the cost of public education, State Superintendent Stetson, of Maine, in a private communication, thus defines the prospective policy of that State: "Local communities shall provide school lots and school buildings, and keep the same in repair. Two-thirds of the money raised for maintaining schools shall come from the State and one-third from the local communities. The apportionment of the money to the several municipalities shall be upon the basis of average attendance. We shall also try to get a law prohibiting towns from receiving State aid, if they maintain schools having less than a certain average attendance." Such a law as this would serve to prevent the undue multiplication of districts, and would even work a certain measure of consolidation.

The distribution of taxes levied on railroads, telegraphs, long-distance telephone lines, express companies, and the like, is an important question. In some States, as New York, Texas, and Ohio, school taxes levied on railroads inure to the exclusive benefit of the districts or townships through which the tracks run, excluding any State tax that may be levied on such property. This rule the subcommittee regards as unjust. The location of railroads is determined largely by physical conditions, and the mere fact that a line happens to run through its territory, where probably not a dollar of the stock or bonds is owned, is no reason why a district or township should profit thereby to the exclusion of other and less fortunate districts or townships.

In Pennsylvania the taxes on railroads are paid into the State treasury and are distributed by the legislature along with other revenues, the public schools, normal schools, and colleges being included among the objects of the appropriation. California has a similar provision. The mode of distributing the Michigan specific tax has already been described. It is believed that such revenues as the foregoing should inure to the common benefit of the State; but what is here said, let it be remarked, in no way relates to pending controversies about the taxation of railroads or other similar property.

The Nebraska law contains one excellent feature that is worthy of mention. All public high schools in the State that, as determined by the State department of education, have a proper equipment of teachers, appliances, and course of study, are open to attendance by any person of school age residing outside the district who is a resident of the State and whose education can not be profitably carried on in the public school of the district of his residence. Such pupil must have a certificate signed by the county superintendent that he has completed the common-school course prescribed by the State department for work below the high school. He must attend at the high school nearest to his residence or at a high school of approved grade in the county of his residence. Any school board that furnishes high-school instruction to such pupil is authorized to charge 50 cents a week for the time that he has been in attendance, and it is made the duty of the county board to pay all such bills out of the county school fund. Massachusetts and Ohio, and perhaps other States also, provide for educating qualified pupils in high

schools in other places than those where they reside, provided there are no home schools for them to attend, and this without cost to themselves. As Massachusetts is the only State that makes the provision of high schools compulsory under any circumstances, it may be well to mention the principal features of the State law in regard to that subject. Every town having a population of 4,000 persons or 500 families is obliged to maintain a high school, the grade of the school depending somewhat upon the fact whether it has the larger or the smaller population. Pupils living in towns that are not required to maintain a high school can attend any neighboring high school that will receive them. In such cases the State pays the tuition of the pupil, provided the valuation of the town in which he resides does not exceed $500,000; if the valuation does exceed that amount the town pays the tuition. High-school tuition is, therefore, wholly free to every qualified pupil in the State.

ORGANIZATION.

The subcommittee is not here interested in the subject of school organization further than it relates to school maintenance. Its relations to teaching, supervision, and studies are topics belonging to other divisions of the general report. The statement and enforcement of two propositions will answer the present purpose.

I. The first proposition is that the township-unit system is far superior to the district system, and should be substituted, if practicable, for that system wherever it exists. The superiority of the town or township as an administrative unit is as great as its superiority as a taxing unit. The principal advantages are the following:

1. If the schools of a township are under a single board elected from the township at large, schoolhouses will far more likely be built where they are needed than under the other system.

2. Equality of school provision will be much more fully secured in respect to schoolhouses and grounds, length of school terms, and the ability and character of teachers.

3. The tendency will not be to multiply schools unduly, but to restrict their number, bringing together more scholars, and thus making better classification, grading, and teaching possible, and increasing the interest and enthusiasm of the pupils.

4. Better supervision can be secured. The county superintendent can deal more effectively and easily with one board in a township than with six, ten, or twelve; while township and township-union supervision will be greatly promoted.

5. Simplicity and economy of administration will be facilitated, and the sense of official responsibility be enhanced.

6. The tendency will be to employ teachers for longer terms, and thereby to restrict, in a considerable degree, the evils that flow from frequent changes. On this point the statistics of Mr. Gass, presented in this report, may be mentioned.

7. The strifes and contentions between districts that are now not infrequent will be prevented.

8. Transfers of pupils from school to school will be made more easy.

9. The reason last to be mentioned is perhaps the strongest of all. The relations of the township-unit system to school consolidation have already been suggested. The township system does not necessitate such consolidation, although it is likely to work that way; but consolidation is almost wholly dependent upon that system; schools will not be consolidated in great numbers if a plurality of district school boards have to do the work.

The subcommittee has stated that the adoption of the township-unit system will be followed by the reforms that have been mentioned. It is not, indeed, meant that such will be the unvarying result. There will be exceptions—perhaps

many exceptions—when the whole country is considered, but the tendency will be strong in the directions named, or such will be the general character of the result. Not only is this the suggestion of common sense, but it is the teaching of experience as well. (Appendix E.)

The town-unit school system was the ancient system of New England. The classic-school law enacted by the general court of Massachusetts in 1648 ordered that the towns should found schools on their reaching a certain number of householders, the teachers to be paid either by the parents of such children as resorted to them for instruction or by the inhabitants in general by way of supply, as those who ordered the prudentials of the town should appoint. The word "township" is also used in the law. Connecticut followed the example of Massachusetts. The original New England town, which was a small concentration of population, was well adapted to this system. But "as the population of each little nucleus of settlement spread itself out from the center of the original 'plantation,' it early became convenient, in Massachusetts and Connecticut at least, to allow neighboring families at a distance from the local concentration, or nucleus, to form themselves into a school district." The original church parishes were divided in the same way. If these districts had been founded merely for the purpose of school supply, or to regulate attendance, there would have been, under the conditions existing, no objection to their formation, but the contrary. Unfortunately, however, these new districts also became units of school maintenance, bodies corporate and politic. These districts appear at first to have existed by sufferance merely, but the celebrated school law of 1789 legalized them, thus paving the way for the general introduction of the new system. Horace Mann declared in his Tenth Annual Report: "I consider the law of 1789 * * * authorizing towns to divide themselves into districts the most unfortunate law on the subject of common schools ever enacted in the State." Still this "act was not repealed until manufacturing had restored those concentrations of population which in the early colonies had invited township control of school affairs." This was finally done. Mr. Mann in the same report (p. 37) bore this testimony to the superiority of the town system:

As a general fact, the schools of undistricted towns are greatly superior to those in districted towns—and for obvious reasons. The first class of towns—the undistricted—provide all the schoolhouses, and, through the agency of the school committee, employ all the teachers. If one good schoolhouse is provided for any section of the town, all the other sections, having contributed their respective portions of the expense to erect the good house, will demand one equally good for themselves; and the equity of such a demand is so obvious that it can not be resisted. If, on the other hand, each section were a separate district, and bound for the whole expense of a new house if it should erect one, it would be tempted to continue an old house long after it had ceased to be comfortable, and, indeed, as experience has too often sadly proved, long after it has ceased to be tenantable.

So, too, in undistricted towns we never see the painful, antirepublican contrast of one school in one section kept all the year round by a teacher who receives $100 a month, while in another section of the same town the school is kept on the minimum principle, both as to time and price, and, of course, yielding only a minimum amount of benefit, to say nothing of probable and irremediable evils that it may inflict. In regard to supervision, also, if the school committee is responsible for the condition of all the schools, it is constrained to visit all alike, to care for all alike, and, as far as possible, to aim in all at the production of equal results, because any partiality or favoritism will be rebuked at the ballot box. In undistricted towns, therefore, three grand conditions of a prosperous school, viz, a good house, a good teacher, and vigilant superintendence, are secured by motives which do not operate, or operate to a very limited extent, in districted towns. Under the nondistricting system it is obvious that each section of a town will demand at least an equal degree of accommodation in the house, of talent in the teacher, and of attention in the committee; and should any selfish feelings be indulged it is some consolation to reflect that they, too, will be harnessed to the car of improvement.

The district system was at one time universal, and it exists in some form in a great majority of the States to-day. In Maine, New Hampshire, Massachusetts,

and New Jersey it has been wholly swept away. In Connecticut and Rhode Island the town system is permissive and exists side by side with the district system. The township system exists in Pennsylvania, Ohio, and Indiana. It is permissive in the upper peninsula of Michigan, in Wisconsin, and in Minnesota, and doubtless in other States. It varies somewhat in the organization of the local authority. The Massachusetts school committee consists of three members, or a multiple of three, elected from the town at large. In New Jersey the board consists of three, five, or nine members, as the town may elect. The Ohio board consists of delegates or representatives elected by the subdistricts, one each. A single trustee elected by the people manages the schools of a township in Indiana, except that he is assisted by a director in each attendance district who looks after incidental local matters.

Considering the great superiority of the township system over the district system, it is not a little strange that its introduction in the room of its competitor should have been so steadily resisted as it has been. This opposition is due in part to the power of conservative habit, in part to the belief that the district system is more democratic, and in part to the popular fondness for office holding, all conjoined with much misconception and ignorance in respect to the merits of the two systems. It has also been urged in favor of the district by politicians that it is the best unit for canvassing the States for political purposes. Certainly it can not be objected to the township system in its pure form that it is not sufficiently democratic. In 1875 there were 15,087 teachers employed in teaching the common schools in Ohio, and there were in the State at the same time more than 35,000 school directors and members of boards of education charged with the administration of the schools. This, assuredly, is an excess of democracy.

The "community" system is much worse than the district system, and fortunately it is confined to a single State. The Texas law permits parents, guardians, or other persons having control of children of scholastic age, residing in any one of the so-called "community" counties (35 in number out of a total of 250), to unite and organize themselves into a free-school community entitled to the benefits of the available school fund belonging to the county, upon complying with certain prescribed conditions. The persons so uniting and organizing first address a petition to the county judge, who is ex-officio county superintendent of schools, duly signed by the petitioners, setting forth that the community is white or black, as the case may be, giving an alphabetical list of the names of children of scholastic age within the limits proposed, describing the capacity of the schoolhouse and the character of the other conveniences that the petitioners have to offer, naming persons to act as trustees, etc. The matter then passes into the hands of the judge, who has no discretionary power in the premises. He may not even throw aside such a petition either because it is signed by few persons or because the alphabetical list carries few names. The law does not fix any minimum number in either case. If the people of a neighborhood desire a school, no matter how few they may be, a school the judge must grant them. The "community" is a voluntary district in the strict sense of the term, having legal existence for one year only, and having no authority to levy a local school tax, and the evils that attend it are far greater than those that call so loudly for the abolition of the district system wherever that is practicable. The people of Texas can, however, congratulate themselves that the "community" school, which plainly originated in pioneer society, has lost ground in later years.

In the South, and in those Western States that have the county system of local government, the only practical alternative to the district system of school organization is a county system. It must be remembered that in these States the town or township does not exist. Fortunately, such a system is not altogether unknown. In a few counties of Georgia it has been in successful operation for a number of

years. These are the principal features of the system as it exists in Richmond County, in which the city of Augusta is situated:

The county is the unit area of organization, and the rural parts and the urban parts of the county district, as far as practicable, are treated just alike. A board of education, composed of representatives elected by the people of the county for the term of three years, one-third retiring each year, manages all the schools. The school tax is levied at a uniform rate upon all the property of the county, without revision by any other authority and without any limit as to rate or amount. The county and State funds are distributed to the schools according to the number of children to be educated. There is no district tax. The same qualifications are required for country and for city teachers. The teachers are treated as nearly alike as the conditions admit, and they are paid about the same salaries. The schools are in session the same length of time in a year, nine calendar months. The country schoolhouses, on the average, are situated 4 miles apart, and no child is out of walking distance of a school open nine months in the year, and taught by a good teacher. One superintendent has charge of all the schools. Augusta has nine-tenths of the taxable property of the county, but only three-fourths of the school population. In other words, the rural parts of the county pay one-tenth of the school tax and receive the benefit of one-fourth of it. For the most part, these are excellent provisions. The county would seem to be the natural area unit for popular schools under the county system of local government. The subcommittee confidently believes that this mode of school organization has a great future before it in the United States (Appendix D).

II. In those parts of the country where existing physical and social conditions render it practicable there should be such a consolidation of rural schools as will diminish the existing number of schools, schoolhouses, and teachers, and bring together, at advantageous points, the pupils who are now divided and scattered among the isolated schools of the township or other similar district. This step should be taken in the interest of good education as well as of public economy. To make this reform possible, the children, as far as may be necessary or practicable, must be conveyed to and from the schoolhouses at public expense.

How absolutely fatal to good schools the existing conditions are in many parts of the country, statistics show most conclusively. State Superintendent Wells, of Wisconsin, reported in 1894 that his State had 183 districts whose average attendance the previous year was not more than 5 each; that 858 others were not above 10 each; while 2,481 more did not exceed 20 each. "In other words," he said, "3,523 country districts, about three-fifths of the total number, have an average attendance not exceeding 20, and about two-fifths above that average, with the great majority near the lower margin."[1]

Mr. H. R. Gass, of Michigan, citing the State report for his authority, states in a published paper that in 1886 the country schools of Calhoun County in that State required 158 teachers, and that they employed 342 different ones in the course of the year. The average length of the school in the district was 8.4 months, while the average term for which the teachers were employed was but 3.8 months. He cites a second county that presents like statistics, and then observes: "The ratio of the number [of teachers] required to the number employed is about the same as this throughout the State, the tenure being longer in the newer than in the older counties." This state of things Mr. Gass attributes to the prevalence of the district system! He refers to Massachusetts and Indiana, where changes of teachers are much less frequent and teachers' tenures much longer than in Michigan. While two teachers on an average were employed in Michigan for a school every year, but few schools in the other States employed more than one. In the same State at the present time there are over 1,000 districts that enumerate less than 25

[1] "The Township System of School Government." Madison, 1894.

children of school age each, while 70 counties contain 468 districts that enumerate less than 15 each. The statistics at hand do not show the actual size of the schools. Nor are the small schools found in the newer and poorer parts of the State only; the oldest and richest counties have their fair share of them. In fact, the newer parts of a State often have the largest and best schools. Not only so, the oldest and most densely populated States frequently make a very poor showing. In 1894–95 there were 7,529 school districts in New York, in each of which the average attendance upon school during the year varied from 1 to 20 pupils, while the average daily attendance in each of 2,983 districts was less than 10 pupils (Appendix I). In 1893 Vermont had 153 schools of 6 pupils or less each. In 1892 State Superintendent Luce, of Maine, reported that the average enrollment in the schools of that State for the previous year was less than 25 pupils to a school, and that the number of districts having less than 25 was larger than the number having more. He declared that there were probably between 1,000 and 1,200 existing schools in the State whose enrollment was 12 or less, and that 600 or 800 schools then existing could be abolished without detriment.[1] Twenty-five years ago a large number of schools on the Western Reserve, Ohio, long famed for schools, had dwindled to the most insignificant size. Still other statistics of similar import will be found in the report of the subcommittee on instruction and discipline. Attention is drawn particularly to those relating to Rhode Island and Massachusetts.

But it is needless to multiply statistics or to insist at length that thousands of rural schools furnish their pupils with a miserable preparation for the duties of life. When we consider the various elements that enter into good education, and especially training for social activities, it is not too much to say that a very small school is almost necessarily a very poor school. The facts are notorious. Hitherto it has been supposed that, although the cities and towns surpassed the rural districts in higher education, the rural districts contained a smaller proportion of illiterate persons. This has been the prevailing view in the Northern States, and probably it was once in accord with the facts. The cities have been considered the great hives of illiteracy. But there is now grave reason to question whether the fact is not often the other way. Certainly it is so in the only State where, so far as the subcommittee is informed, the subject has been statistically investigated.[2] But however this may be, a remedy for the unsatisfactory state of the rural schools is one of the pressing needs of the day. What can be done? One thing that can be done is to consolidate many of the small schools by carrying back and forth such pupils as need to be carried, and thus, by one stroke, create several of the conditions of good schools. The interest that this subject is beginning to awaken is one of the hopeful signs of the times.

---

[1] Quoted by Mr. Gass. See "Transactions of the Michigan State Teachers' Association, 1887."

[2] The State referred to is Michigan. According to the State census of 1894 the ratios of the foreign-born persons in the cities of the State, 10 years of age or more, unable to read and write, and in the State at large, were practically the same, 84 in 1,000. But the ratios of the native-born in the cities, in the State at large, and therefore in the country districts, were quite different. In the cities it was 14 in 1,000; in the State at large, 21 in 1,000; in the country, 24 in 1,000. For every 14 persons 10 years of age or upward in the cities unable to read and write there were 24 in the country; that is, the ratio in the country is 70 per cent greater than that in the cities. If the country rate of illiteracy could be reduced to the city rate, the number of illiterates of the native-born population 10 years of age and upward unable to read and write would be reduced about 8,000. Several facts, no doubt, enter into the explanation of the greater illiteracy of the country districts, but the most important of them is the inferiority of the country schools. It does not explain matters to say that Michigan is comparatively a new State; that much of it is thinly settled; that it contains large lumbering and mining districts, etc. The fact is that in the oldest and wealthiest parts of Michigan the cities, as a rule, surpass the counties in which they are situated in respect to popular intelligence. The city of Detroit ranks distinctly higher than Wayne County, and the same may be said of the cities of Grand Rapids and Ann Arbor as compared with Kent and Washtenaw counties. The counties named contain the cities mentioned.

It was Massachusetts that led the way in developing the district system, and it is Massachusetts that is leading the way in consolidation. An act that dates from 1869 authorizes any town in the Commonwealth to raise money by taxation to enable the school committee, in its discretion, to provide for the conveyance of pupils to and from the public schools at public cost. The towns were already empowered to build schoolhouses wherever they were really needed. Availing themselves of these powers, many towns have entered upon the work of consolidating their schools. How the work goes on is shown by the following table exhibiting the sums of money paid for public-school transportation for a series of years:

Year.	Amount.	Year.	Amount.
1888–89	$22,118.38	1892–93	$50,590.41
1889–90	24,145.12	1893–94	68,617.66
1890–91	30,648.68	1894–95	76,608.29
1891–92	38,726.07	1895–96	91,136.11

The movement has extended beyond Massachusetts and reached every one of the New England States. In these States many hundreds of schools have been consolidated, and with the most gratifying results. Occasionally an unsuccessful experiment is reported, but the great stream of testimony runs strongly the other way. Longer school terms, better teachers, better grading, better instruction, more interest in the pupils, greater physical comfort on the part of the children, better supervision—these are the claims that are made for the new departure (Appendixes E and F). Other things being equal, the new way is never more expensive than the old one, and often it is less expensive.

The movement has spread beyond New England. In 1894 a law was enacted in New Jersey providing for the transportation of pupils at public expense in order that rural schools might be consolidated with city ones. A most interesting experiment in consolidation is being tried in northeastern Ohio, where some schools had already died out and many more were lingering on the verge of death. Permissive legislation has been obtained in several counties, and already many townships are working the plan successfully, while many others are looking on expectantly and are apparently on the point of making the new departure. The newspapers are quick to note the innovation, and it is already attracting attention beyond the borders of the State (Appendix F).

The distinct pedagogical advantages of consolidation are much more fully set forth in the reports on supply of teachers and instruction and discipline than here. In this report the topic is dealt with mainly as it is related to organization and administration. The fact is, however, the several aspects of consolidation are inseparably connected. As a rule, whatever promotes simplicity and ease of administration promotes good instruction, and vice versa. No one of the subcommittees that handle the subject for a moment supposes that there is any charm in the word "consolidation" to cast all the evil spirits out of the rural school, but they all believe, after giving the subject mature consideration, that great possibilities of improvement lie in that direction. It is perfectly true that the consolidation remedy can not be universally applied, because physical and social conditions often forbid. The fact is that a large proportion of the children of the land will be schooled in little schools—rural schools, ungraded schools—or they will not be schooled at all. Suggestions looking to the improvement of these schools will be found in the reports of all the subcommittees, but insistence is here placed upon the fact that the consolidation remedy can be applied on a grand scale, with the largest promise of success.

In most States some new legislation will be necessary to that end, but not in all.

Wherever the township-unit system exists, the first step, and the long step, has already been taken. In such States it should not be difficult to secure the needed legislation in relation to transportation. State Superintendent Emery, of Wisconsin, has already notified the people of his State that the laws contain all the provisions that are necessary to enable them to move at once in the direction of school consolidation.

It is important that the consolidation reform shall not be misunderstood. It does not necessarily mean that there shall be only one school in a town or township. It does not mean either that parts of different townships or counties shall not be comprised in one school. These questions are merely matters of detail, and their adjustment will depend upon such factors as the size of townships, the distribution of villages or other local centers, the direction and condition of roads, streams, and bridges, the distribution of population, and the physical configuration of the township and the adjacent parts of the country.

It is noteworthy how the different phases of educational reform all tend to hold together. In the Northern States the cause of school consolidation depends intimately upon the adoption of the township-unit system. A certain amount of consolidation can be effected by the abolition of small districts; it may be possible, also, for several independent districts to merge their schools into one, for the time at least, and still preserve their independence; but it is manifest that the first plan will not prove effectual and that the second one will be infrequent and precarious. The subcommittee believes confidently, therefore, that the fortune of effectual consolidation is closely bound up with the fortune of the township-unit system.

It is also noteworthy, let it be remarked again, how different social elements tend to attract one another and so to coalesce. School consolidation, especially its practicability, turns largely upon means of cheap, safe, and easy communication throughout the school area. Here we touch a question intimately relating to social progress that has been receiving increasing attention the last few years. Reference is made to the improvement of roads. Those who have been promoting this movement have not probably regarded it as a measure of educational reform; but such it is. Perhaps there is no rural interest of a social nature that would be more decidedly enhanced by good roads than the educational interest. The people of some of the towns of Ohio, where the new plan is being tried, claim this as a decided advantage, that the drivers of the omnibuses serve as carriers for the mails between the farmhouses and the post-offices, thus promoting the diffusion of intelligence in still another way.

Only a single point remains to be pressed, but it must be pressed strongly. This is the necessity of lengthening materially the time that the country schools on the average are in session each year and the securing of a more regular attendance of the pupils. The legal years now vary widely in different States, and the practical or real years still more widely. Some communities always surpass the legal minimum of time, others as regularly fall below it. In the thickly settled States of the East the rural schools are in session eight, nine, or ten months in the year; but often in the South, and sometimes in the West, one-half the shortest of these terms is not reached. The legal year is frequently absurdly short. Until two years ago the Michigan year was but three months, and now it is but five months. It is quite unnecessary to argue that short schools are, evenly relatively, poor schools. In order to have a good school it is necessary not only to bring pupils together in considerable numbers, but also to hold them to the work a certain number of hours each day and a certain number of days each year. There must be a concentration of effort as of pupils. It is as wasteful a method of education to send children to school seventy or eighty days in the year as it is to send them two or three hours in the day. Persons interested in popular education, and particularly in rural education, should not rest therefore in their efforts until they

have made the legal school year in every State at least one hundred and sixty or one hundred and eighty days.

But it will not be enough for the State simply to fix a minimum school year; it must see to the enforcement of the law. The law should hold communities to a rigid accountability in respect to maintaining schools of legal grade for the full legal periods, to employing none but certificated teachers, and making all the required reports to the State educational department. Most school laws contain such provisions as these, but it is feared that they are not always enforced. The only practicable mode of enforcement is absolutely to withhold from the local organizations all aid from the superior taxing units, as the State, until they first observe the law.

And again, it will not suffice for the State to see that the prescribed quality of instruction is actually furnished. It might perhaps be thought that if the State only provided local schools and made them free the people would be only too glad to avail themselves of them to the full, but sad experience shows that this is not always the case. The indifference, ignorance, and selfishness of some parents come between their children and the schools. In communities where the school attendance is compulsory some parents are in an almost constant battle with the authorities to keep their children out of the school as much as possible. It is possible that such extreme indifference or selfishness as this is more common in cities than in the country; and yet it is true, as a rule, that the country child's labor, especially the farm boy's labor, has a greater money value than the city child's labor, and that the farmer is therefore under a special temptation to keep his boys out of school. On the whole, there is quite as much need of an efficient compulsory attendance law in the country as in the city, and perhaps more.

The subcommittee has not taken space to discuss, in general, the common education that the American States are now furnishing the American people. That is a large subject, and for the most part lies outside the field of the present inquiry. It will suffice to say on this large question that the people had better pay what they do pay for what they get than to go without it, or even twice, thrice, or four times the sum; but at the same time they might receive and should receive a great deal more for their money than at present. This is particularly true of the rural schools. No doubt there are many excellent schools in the country, but on the whole it may well be doubted whether any money that is expended in the people's interest is expended more wastefully than what goes to the country schools. No doubt the country school has points of advantage over the city school, as the freer communion with nature, but on the whole it is inferior. The typical "little red schoolhouse," so invested with sentiment, is a costly and unsatisfactory institution of education. Owing to social changes, in many parts of the country it is much less efficient and useful, at least relatively, than once it was, and a new organization is imperatively called for. Something should be done to stop the wasteful expenditure of the public money. State Superintendent Stetson, speaking for his State, puts the case thus in a communication to the subcommittee:

I have devoted quite a number of pages in my report [1895] to showing the people of Maine that we are wasting an enormous sum of money in this State because of the unbusinesslike methods which are used in the expenditure of its school funds. This waste is made in every direction in which money is spent. We pay more than we need to for school lots, the erection of school buildings, the furnishing of school appliances, text-books, fuel, making repairs, etc. The waste along these lines aggregates more than one-third of a million of dollars each year. I have shown in the report that the money which we spend for common schools is sufficient to maintain schools taught by professionally trained teachers and superintended by competent superintendents; that in addition to doing these two important things we would have money enough left to supply them with the appliances necessary for a successful school, and also furnish the needed apparatus, library books, and make all the needed repairs and additions. I feel that I have demonstrated this point so that there will be no further question about it in

the State of Maine. The whole matter turns upon the simple point that we are alarmingly wasteful in our expenditure of school money.

Personally I am in favor of local communities being responsible for providing school buildings. I think two-thirds of the funds required for the maintenance of the common schools should be furnished by the State, and that the other third should be raised by local taxation; that the State should examine all teachers and issue all licenses to teach; that towns thus receiving State aid must employ teachers who hold such certificates. The State should inspect the school accounts of the towns receiving State aid.

The subcommittee deems it advisable, now that the whole ground has been covered, to restate the fundamental propositions that have been urged in this report. These all start from the one central postulate that a provision of funds sufficient for their adequate support is essential to the existence and life of good schools. The threefold division of the subject will be preserved in the summary.

I. REVENUE.

1. The great resource of the public schools is, and must continue to be, some form or forms of public taxation.

2. Such areas or units of taxation should be created, or continued if already in existence, as will fully develop the sound American principle that the whole wealth of the State shall be made available for educating all the youth of the State.

3. To accomplish this end, resort must be had to the larger units of taxation, especially where population is sparse and wealth meager. The following recommendations must be specifically urged: (1) A liberal provision of funds from the State treasury; (2) a county tax in at least all the county-system States; (3) a town or township tax in the States where this civil division exists; (4) taxes in special districts; that is, in cities and villages. The school district, in the commonly accepted sense of that term, is not a desirable taxing unit, but quite the contrary, and should be abolished as such unit.

II. DISTRIBUTION.

1. Funds raised by the large political or social units for general school purposes should be distributed in such a way as to bring the rich and the strong to the help of the poor and the weak.

2. Such rules of distribution should be adopted as will accomplish this end. In order to do this, distribution must be based, to a certain extent at least, upon fixed or arbitrary units; that is, so much money must be given to the school or to the teacher.

3. The large taxing units should render assistance to the small ones only upon the condition that the small ones first do something for themselves.

III. ORGANIZATION.

1. In the States where the town or mixed system of local government exists, the town or township school system should, as far as practicable, be substituted for the district system; in the county-system States the county-school system is the natural alternative to the district system.

2. In those parts of the country where existing physical and social conditions render it practicable, there should be such a consolidation of rural schools as will diminish the existing number of schools, schoolhouses, and teachers, and bring together, at advantageous points, the pupils who are now divided and scattered among the isolated schools of the township or other similar districts.

3. There is urgent need of lengthening materially the time that the country schools, on the average, are in session each year. The ideal should be a minimum school year in every State of at least one hundred and sixty or one hundred and eighty days.

The subcommittee does not expect to see, and does not desire to see, the school systems of the country all brought to one uniform pattern. It is too well aware of the great diversity of conditions that exist to think such a thing is possible. Even more, a certain variety, and so conflict, of systems is conducive to life, activity, and improvement. Neither is the subcommittee under any illusions as to what is possible, or probable, in a field of education so vast as that offered by the United States, with the great number of authorities, State and local. At the same time there are certain general laws governing successful school systems and schools that can not be ignored. Some of the principal of these laws have been set forth above; and it is believed that their general recognition will be followed by a marked improvement of the common schools, and so of the popular education of the country.

Some persons may ask, "How shall the principles laid down in this report be made practical?" "How shall they be established in communities or States where they do not exist, or exist only in part?" To these questions only a general answer is needed. The State legislature, the lawmaking authority, is the only source of power in relation to education, as well as in relation to all other branches of the State government. Accordingly, if the school law is defective and weak, the legislature must be called upon to repair and strengthen it. No progress can be made without an efficient law and efficient school authorities.

But how shall the legislature be induced to act in the premises? In precisely the same way that it is induced to act in other matters. Facts, arguments, persuasion, must be addressed to the members of the legislature. Above all it is important that the public mind shall be informed as fully as possible upon all branches of the subject. If the people generally knew how much better schools they might have than those that they do now have, and for no more cost, it is impossible to believe that they would not bestir themselves to effect reforms. The subcommittee marks out what it believes to be broad lines of educational progress. It enforces its views, as far as possible, with appropriate arguments. But it must necessarily leave the application of these views and arguments to the exigencies existing in particular communities or States to such persons, belonging to these communities or States, as are interested in the subject and are familiar with all the local facts and conditions.

B. A. HINSDALE, *Chairman.*
W. S. SUTTON.
S. T. BLACK.

REPORT OF THE SUBCOMMITTEE ON SUPERVISION.

The subcommittee on supervision of rural schools has taken into careful consideration the various topics submitted for investigation. Its inquiries have extended into all the States and Territories except Indian Territory and Alaska, and the facts are based on returns more or less full from all parts of the country.

Professional supervision is to-day regarded as an essential factor in our school system. It has been observed that the schools that are closely supervised by men who thoroughly know their business at once respond to the influence of this supervision. Expert supervision has resulted in systematic, orderly, and well-directed instruction. It is a matter of remark that the most competent superintendents have the best schools, and that cities noted for their excellence in school work have attained this preeminence through the medium of intelligent supervision. This is also true of those counties which have come under the same influence.

"There is no other agency in our school system that has done so much for the improvement of our schools in organization, and in methods of instruction and discipline, as the superintendency."

The attention of the profession, however, has been mainly directed toward

expert supervisions in city schools, and but little heed has been paid to the demand for such work in rural districts. It is quite time that our inquiries should be directed toward the character of the supervision demanded by the country school. If supervision through a competent superintendent is a good thing for city schools, there is every reason why it would be a good thing for rural schools.

STATE SUPERINTENDENT.

Although the State superintendent stands at the head of the public-school system of the State, his work is more closely related to rural than to city schools. As this report has reference only to the conditions of rural schools, your subcommittee will consider the duties of this officer as bearing upon that part alone of the general school system. No officer connected with the administration of State affairs requires higher or more essential qualifications than that of superintendent of public instruction. He should be a man of high moral character, well acquainted with approved methods and with the history and condition of education in his State. He should be in close touch with the educational spirit of the times, and should be one whom the profession regards as authority in all that constitutes excellence in school matters. It is also agreed that he should be an experienced teacher, of broad and thorough scholarship, and a good public speaker. With these qualifications there should be combined a large share of good common sense, and sufficient executive ability to manage the details of his office.

The legal term of office in Massachusetts and Rhode Island is one year. In Connecticut it is at the pleasure of the State board. In twenty States the term of office is two years; in four States, three years; in seventeen States, four years; but in no State does it exceed four years. The average length of term of the State superintendent is two years and ten months. The lowest salary paid is $1,000 and the highest $5,000 per year. The average salary is $2,475 per year. In answer to the question as to how much time the State superintendent devotes to supervision of schools, we had definite answers from thirty-seven States, in which we find that nineteen of these superintendents devote more than half of their time to visiting schools and traveling in the interest of education, and eighteen devote less than half their time. Quite a number of the State superintendents report that they divide their time equally between the office work and supervision. In only a few of the States does the State superintendent exercise no supervision, and in several the supervision is carried on through deputies or agents.

The State superintendent under present arrangements has but little time for personal inspection of school work. The superintendents in fourteen States visit each county once a year and in eight States once every two years. From the other States no definite information could be obtained. Many superintendents say, as often as practicable; in some instances, not at all. Our information is to the effect that most of the State superintendents devote as much time to supervision as they can spare, but that it is generally considered secondary to work of a clerical nature. There are undoubtedly in some States sections which have never been visited by the State superintendent or his deputy.

By some means the influence of the State superintendent should be extended until it reaches every rural school in the State. In all possible ways the office should be made useful to the teachers and school officers. The rural schools need this stimulating, helpful influence more even than those of the city. While in most States the office has but little more than advisory powers, yet, through lectures at associations and through the inspection of institutes, the State superintendent ought to be able to convince the teachers of rural schools that he is in close sympathy with their work.

The work of the State superintendent ought to be made more effective by so increasing his clerical force as to enable him to spend more time in direct contact

with the schools and school officials of the State. The careful compilation of statistics is very important, but it can be intrusted to a skillful statistician, while much of the routine work of the office can be well done by clerks. The higher and by far the more important work of directing educational movements, of instructing the people, and of creating public opinion and arousing public interest devolves upon the State superintendent. There is a general demand for more assistance in his office, longer tenure of service, and more liberal financial support. His work should be so related to that of the superintendents in the various subdivisions of the State for school purposes that the whole may be properly articulated, and the county or town superintendents be under his direction and control. He should come in frequent contact with them by conventions held for the purpose of instructing them in their particular duties, and should send them such circulars and letters as may be necessary to aid and direct them in their work.

The State superintendent should have the power to withhold the State appropriation from all counties or school districts not complying with the law in every particular, because he would then hold the key to the situation and could enforce his orders.

The main duties of the State superintendent are not only to organize and direct educational influence and laws already existing, but also to go among the people in the spirit of Horace Mann, and, by public addresses, by the liberal use of the press, and by securing the assistance of the leading men of the State, to arouse and keep alive an interest in the cause of popular education. In connection with the rural schools especially the State superintendent not only has great possibilities for a wise supervisory influence, but also great opportunities to arouse and instruct the people.

In a majority of the States the most needful legislation is that which bears upon the organization and maintenance of rural schools, and a supply of competent teachers for the same. The State superintendent, therefore, should be a man able to secure the cooperation of the legislature for the enactment of proper statutes. This can be done only by one who sees clearly the great needs of the school system, and who is able to go before the people and the legislature and unite all influences to obtain the necessary legislation. While putting into this high office any person solely through his political affiliations is to be deprecated, the State superintendent should be a man who knows how to approach the leaders of all parties and convince them of the justice and soundness of his plans, viewed from the high vantage ground of the general good.

COUNTY, TOWNSHIP, OR DISTRICT SUPERINTENDENT.

A still more important question opened for discussion is the character and degree of supervision below that of the State superintendent.[1] Thirty-eight States, mainly in the South and West, have county superintendents, whose duty it is to visit the schools and exercise the duties usually belonging to their office. The New England States generally have what is known as township or district supervision, which arises in large part from their political organization. In New England the town is the dominant political unit, while in the South and West it is the county. The simplicity and effectiveness of supervision are promoted when the units of political organization and of school administration are identical. This condition has its limitations, however, in the amount of territory to be covered and in the density of population, which is a varying quantity. The main point is to bring every rural school of the country as far as possible under the watchful care of a competent supervising officer. Responsibility is a strong

stimulant. It is one of the weak points in our present system that too often the rural school-teacher is responsible to no one.

In regard to the operation of the two principal methods of supervision, there is no reason why any section should abandon the practice which has been found best adapted to its peculiar conditions. It must be conceded, however, that a single township, containing on an average ten or twelve schools, is too small a territory to engage profitably the entire attention of one person. In such a case one of two things must necessarily happen: Either the schools are supervised to the point of interference, or the supervision becomes uncertain, feeble, and unsatisfactory. In a general way, the rural township is too small a supervisory unit. Wherever it has been tried the supervisor has generally had some other business to attend to, and thus his work has been found wanting in those results which are most desirable. In order that the work of overseeing and directing may be effective, it must engage the entire time and the best thought of the supervisory officer.

A proper remedy for this is the combination of towns for supervisory purposes. Three, four, or five towns could be united in one supervisory district until a sufficient number of schools have been secured to engage the entire attention of one good man. The burden of his salary could be borne by these towns in the proportion of the number of schools they contribute to his work. This plan is in operation in Massachusetts, and has been satisfactory. A complete exposition of the Massachusetts plan of supervision of township schools is found in A. W. Edson's monograph, "Supervision of schools in Massachusetts." (Boston, 1895).

In that State 253 of the towns are supervised by 155 supervisors. While some of the large towns can alone support a supervisor, several of the smaller ones must unite to secure the services of an efficient officer. In addition to what the towns do for themselves, the State grants to those of low valuation, when they combine into a supervisory district, the sum of $750 to pay for a supervisor. These towns, however, are required to raise an additional sum equal to that furnished by the State, thus insuring a sufficient sum for the employment of an expert schoolman. By these means 93 per cent of the children of Massachusetts have been brought under close supervision. The salary paid to a supervisor is at least $1,500 a year, and he is enabled to devote all his time to the work and to inspect each school once a month. It is true that there are still about one hundred towns in Massachusetts without supervision, yet the feasibility of cooperative supervision with aid from the State is proven beyond all doubt.

"The State aid to a district amounts at present to $1,250—$750 toward the superintendent's salary and $500 toward the salaries of the teachers. The remainder of the superintendent's salary, $750, must be raised by the towns of the district. They are at liberty, of course, to raise more than $750 for the purpose, if they desire to do so." (Massachusetts State Report, 1895.)

What has been said regarding the combination of towns for supervisory purposes can be repeated with equal emphasis as to other small divisions of territory termed "school districts." The same principle applies here as elsewhere, that the interests of the schools included in a given territory should be sufficient to warrant the employment of a thoroughly competent person at such a salary as would justify devoting his entire time to his work. After all has been done, there will still be vast sections of country, especially in the West and Southwest, without any means of efficient supervision. No present remedy can be devised to aid them. It can be safely left for the several States, as population increases, to look after the interests of the schools in the light of the experience of older communities about them.

The worth of the county superintendency is acknowledged. but in many cases the county is too large an area and contains too many teachers for one man to properly supervise. The county is as much too large a unit for supervisory purposes as the township is too small. This remark, however, does not apply to every

county nor to any one State. In counties where the number of teachers is too large for one man to supervise the county superintendent should have one or more assistants or deputies to aid him in his work. They should be directly responsible to him for the kind and character of their work, and should be charged solely with supervisory duties. The importance of having one superintendent for the county or district to whom other supervisors are responsible must be emphasized, as it would be an error and a fruitful source of strife if in any territory there should be two or more supervisors having concurrent jurisdiction.

THE COUNTY UNIT.

Since this report is a symposium of suggestions for supervising rural schools, it may not be amiss to discuss a plan of supervisory organization that has found favor in some few counties that contain large cities as well as a rural population. We mention it here because it has valuable features for supervising the rural schools. There is but one school board for the entire county. One set of men legislates for the whole area, and it is their duty to relate the urban and suburban and rural schools into a sympathetic system. This is based upon the idea that every city is bound to respect the people that immediately environ it. It is to the interest of a large city to have good roads leading to it, good crops in the fields around it, and good schools to which the farmers may send their children.

With this as a foundation principle there is but one school fund for the entire county, raised by taxation upon all property in the county, whether it be in or out of the city. This makes the general school fund, which is distributed upon the basis of school population and according to the needs of the city wards and the rural communities. The same qualification for teachers is required whether they teach in a city graded school or in a country ungraded school, and the same salary is paid to them and in the same way and for just as long a term. In this system one superintendent is in charge of the whole area. He looks after a city graded school one day and the next day may be 20 miles away inspecting a country school. Expert supervision by a superintendent and his assistants is thus extended into the rural districts, and both city and country school receive the benefit of what there may be in each that is of real value.

Upon this plan, as a matter of course, a large portion of the school fund raised by taxation on city property is annually distributed to the country schools. The city is really made to assist in supporting the rural schools around it. And who shall say it is not a good thing for the city to do, especially in agricultural sections, in which the education, liberal and special, of the farmer's child is the probable salvation of the farming interests of the country? We should not lose sight of the truth that the farmer's child is to be made a useful citizen, not only content to stay in the home in which he was born and reared, if that is best, but fitted to fill honorably any station in life to which he may be called. To do this he must have all the opportunities of education and culture that the city affords. This can be brought about in no other way than at the city's expense, for wealth is massed in our populous centers. The expert supervision, the well-trained teacher, the long term, the modern text-book, the good schoolhouse, can be placed at the farmer's door by the agencies of the neighboring city, that owes him this and much more (Appendix D).

TRAINED TEACHERS NEEDED IN COUNTRY SCHOOLS.

Supervision is one of the vital needs of the rural schools, since most of their teachers are inexperienced. The number of normal-school graduates in rural schools is lamentably small. The reason is that the normal-school graduate can obtain a better salary by teaching in a larger field. The demand for this class of teachers makes their salaries so high that the country schools can not afford to employ them. As soon as teachers become proficient by reason of experience

acquired in rural schools, the probabilities are that they will be induced to seek better positions in cities where their experience and abilities will command higher salaries.

Add to this the other fact that many young men begin to teach as a stepping-stone to some other profession, and while they are teaching a country school are studying law or medicine, and their hearts are with that rather than with teaching; and also add that many young girls teach until they marry, or as long as they are compelled to teach, and no longer; that they have no real love for their work and no wish to stay in it, and we see how the problems multiply.

Rural schools suffer from lack of trained teachers. In them, as a general thing, are young graduates from the village high school, or some favorite among neighborhood families, or a type of ancient teacher whose placid life is not disturbed by the vexing problems of his profession. This raw material must be developed, made shapely, orderly, and systematic, if time is to be saved to the children, and schools properly supported. A bright and live supervisor will bring order out of confusion, harmony out of discord, and will give life and beauty to that which before was inert and ungainly.

Teaching is a great art, based on a profound science. The supervisor is the expert who has given this art and science his careful attention and whose business it is both to know how to teach and to show others the way of teaching. He can in some measure compensate for the lack of skilled work in the school by closely supervising and guiding inexperienced teachers and showing them what to do. An expert is one who possesses skill gained by practice. A supervisor who claims to be an expert should have experimental knowledge of "the how to teach." He is supposed to have given careful attention to those things which characterize a good school. Not only must he know how to teach, but he must know how to instruct others in the art and science of teaching. He must be a skilled teacher of teachers. Without this directing spirit, schools must necessarily suffer until teachers happen upon some better way. It is a great misfortune for schools to wait for wisdom in teaching until the many mistakes of teachers have pointed out better methods. The presence of skilled supervision has been the salvation of many schools.

It is one province of supervision in the country school to bring teachers into contact with each other, to illustrate better ways of teaching, to break up the isolation and monotony of rural school life, and to take to the doors and homes of people and teachers alike the life and freshness which have been the result of research and study on the part of the best minds in the profession. The province of supervision in rural schools falls far short of its legitimate purposes when it begins and ends in the schoolroom.

This point is not sufficiently well appreciated by those who have the oversight and care of schools scattered over a large tract of territory. Country schools have an environment of their own which should neither be forgotten nor ignored. The best supervisory work is that which brings into the rural school everything in farm and rural life which is strong and pure and wholesome. It is possible for the supervising officer so to exert his influence as to give grace and dignity to each individual school and make it the rallying point for every good influence, a blessing to the entire community in which it is situated.

Attention is here called to the fact that in general but little care is taken in the selection of officers chosen to look after the interests of the rural schools. In the majority of States the county superintendents are elected by the people of the county without any regard to the preparation or qualifications they may have for the work. Very few States require the superintendents to have any special qualifications, and in many instances supervisors are put in charge of teachers who know more about teaching than they do, and are required to hold examinations that they themselves could not pass. Add to this the fact that the superintend-

ents are generally paid very small salaries (average, $328 for the whole country) or a meager per diem, and that many engage in other business and regard supervision of schools as an incidental matter, and it becomes apparent that professional supervision is too often the exception rather than the rule.

WORK OF SUPERVISORS.

We need everywhere trained superintendents of schools. "Supervision of schools should rank next in importance to the instruction in schools; indeed, so necessary to successful instruction is competent supervision that the two should receive together the watchful oversight of the State" (New Jersey State Report, 1894). Supervisors should know as much of teaching as the teachers under them, and should be able instinctively to distinguish good teachers by their manners, dress, speech, disposition, and character. The best work of a supervisor is his skill in selecting teachers. Not by the results of examination alone, for some learned people make poor instructors; not by yielding to the pressure of family or political influence, for this will ruin any system of schools; not by selecting his own friends or favorites, for this is unworthy of his office; but by following the knowledge that comes to him through study, by long experience, by careful observation, and by conscientious conviction, which enables him to know a teacher when he meets one, though he may not be able to tell why.

Teaching is a matter of both disposition and knowledge. The former can not be examined, but it ought to be recognized; careful supervision will aid in developing it. Skill in doing this is an essential characteristic of a good supervising officer, especially in connection with rural schools. If the cry is raised (and it is) that there is not enough money to pay for professional supervision, the reply is that it would be wiser to have fewer teachers in order that those employed might be better qualified. A supervisor who is an expert can so arrange and organize the system that a less number of teachers can do the work and do it better, because each one is thoroughly competent. "A good superintendent earns many times his salary; a poor superintendent is too dear at any price. The work of supervision may be unsatisfactory either because the number of schools is too large for the oversight of one person, or because the supervising officer lacks the talent for molding, inspiring, and directing the work of others" (Pennsylvania State Report, 1895). Underpaid supervision is often unskilled and inefficient, and against this we raise our decided protest. Such supervision is of no value whatever to the schools—a penny-wise policy that economizes in the wrong place. A supervisor should have no other business than to care for the schools. He should not be a merchant, nor a lawyer, nor a farmer, nor an active teacher. His business should be to supervise the schools of his county, or township, or district, or whatever his area be called.

With a given sum of money for school purposes, to devote a part of it to skilled supervision will bring more children under enrollment, better teachers in the community, better instruction in the schools, and more satisfaction to the people, than if all the money were spent in paying the salaries of teachers.

In twenty-eight States the supervisors are required by law to visit each school twice a year, in the other States they are allowed to visit the schools as often as practicable. In one or two States the supervisors visit the schools very seldom. The length of time the supervisor spends in each school varies from fifteen minutes to one-half day. The time seems to depend very largely upon circumstances, the number of pupils, the character of the teacher, the efficiency, and the pay of the supervisor. A skilled supervisor inspecting an intelligent teacher can do more service in fifteen minutes than an unskilled supervisor visiting a poor teacher can do in a whole day. The average time spent in the ordinary rural school by the school supervisor is about one hour every year.

In twelve States the supervisors devote all their time to the work. In these

States the average salary is $1,002 a year. In fourteen States the supervisors devote only a part of their time to supervision, with an average annual salary of $408. Sixteen States report that in some counties the supervisors devote all their time to supervision, while in other counties the supervisors devote but a small part of their time to that work. In these States the salaries paid supervisors vary from $100 to $2,000 or $3,000 a year. Where good salaries are paid they devote all their time to supervision. Where small salaries are paid they devote but little time to this special work. All States have some supervision, though it varies greatly in amount and in efficiency.

In many sections of the country a supervisor not capable of suggesting to teachers better methods of teaching and not able to detect false methods pays only a perfunctory visit to the schools. He merely sees whether the building is clean, whether the children look bright and interesting, whether the enrollment is good, such facts as would be noticed by any person of ordinary common sense. Too often the contact of the average supervisor and the teacher of the rural schools is nothing more than a mechanical business performance, with such elements of aid and encouragement as any intelligent visitor may give the school. Although this is not without advantage, it falls far below the standard of professional supervision.

How many teachers a supervisor can direct can not be discussed except in a general way. Schools are more widely separated in some localities than in others, roads are better, teachers are better, and supervisors vary greatly in the rapidity with which they work. As a general rule, however, every rural school ought to be visited at least once in two months. Supervision can not be called close that does any less than that, and it would be better if the schools could be visited once every month.

No accurate information can be gained concerning the conditions of the school, nor can the proper influence be exerted over teacher and pupils, unless the supervisor has time at his disposal to make a reasonably thorough examination of the school and its surroundings. Sometimes, with an inexperienced teacher, he may find it necessary to spend the entire day in the school, while in other cases he may be able to visit two or more schools in one day. The point is that he must not feel compelled to shorten his visit, or to leave his work half done, in order to meet other engagements. To make his visits effective in the highest degree requires time and patience. The length of his visit must depend upon the necessities of the school, and of these he must be his own judge. An ideal system of supervision would give one supervisor from fifty to seventy-five teachers to supervise. Where the number of teachers is greater some will be neglected, for a supervisor generally has many interruptions in his work, such as rainy days, holidays, and the demand upon his time for office work, board meetings, committee meetings, public addresses, etc., so that it is impossible to put in every day in supervision. Allowance must be made for other important duties.

Attention is also called to the power which the supervisor can exert through rightly conducted teachers' meetings, institutes, associations, and round tables. Here he may meet the teachers under his direction, and make use of the information which he has gathered in visiting their schools. From free and open discussions by the teachers he will get an insight into their habits of thought and their methods of expression. Such meetings help break up the unsocial character of rural teachers by bringing them into contact, so that each learns something from the experience of all the others. In this way teachers and supervisors become better acquainted, gather fresh courage and new inspiration, and go home feeling that they have much in common, and that, if they will, they can in many ways be mutually helpful. The most deadening influence about the country school is its isolation. Nothing is more potent in overcoming this than frequent gatherings in which teachers, school officers, and parents freely discuss matters of common interest. To encourage such meetings is one of the duties incumbent upon

the supervisor. Without being too prominent, he may still be the inspiring spirit, guiding, directing, and stimulating the tone and energies of all who participate in the proceedings (Appendix P).

LEGAL REQUIREMENTS AND QUALIFICATIONS.

The necessity of establishing some qualifications to be required of those who are to occupy the position of supervising officer is emphatically insisted upon.

"If it is desirable to insist upon a certain degree of qualification for a school-teacher in the humblest district of the State (this proposition has passed beyond the realm of discussion), it would seem that there is no question that the superior officer clothed by statute with such extended powers as a school commissioner ought to be a person possessing some fixed qualification for the performance of the duties of his office. The schools of the State will never reach that degree of efficiency which the State has a right to demand, and which is expected from the generous provision made for their support by the people, until this evil is corrected. Some standard of qualification should be insisted upon, and the power of removal in case of the election of a person not possessing these qualifications should be vested in the State superintendent." (New York State Report, 1895.)

In only seventeen States are there any qualifications, beyond that of being a resident and a voter. In some States a first-grade license is required, in others a normal or university course, and again in others he must be an experienced teacher. In a majority of the States, however, the electors are allowed to choose any person without regard to educational qualifications.

In answer to circulars of inquiry the following information was obtained regarding supervisors:

Wisconsin: By the law of 1895, must hold a university, normal, State, or special superintendent certificate.

New York: No standard of qualification.

Pennsylvania: Must hold a college diploma, or a State or local certificate; must have at least three years' experience in teaching.

Michigan: Must be a graduate of a reputable college, university, or State normal college, or must hold a State or first-grade certificate.

Mississippi: Must hold a first-grade certificate.

Texas: Must be a person of educational attainments and hold a first-grade teacher's certificate.

Tennessee: Can be appointed only from applicants who pass an examination on questions sent out by State board.

Georgia: Must pass a satisfactory examination.

Louisiana: Must have a common-school education.

Montana: Must hold a first-grade certificate and have one year's experience as teacher.

South Carolina: Must be able to conduct a teachers' institute.

Kentucky: Must be able to obtain a first-class teacher's certificate, hold a State diploma, or State certificate.

Arkansas: Must have a first-grade certificate.

Maryland: The county school board may require applicants to be examined by the State superintendent.

Utah: Must have a valid certificate not lower than the grammar grade.

West Virginia: Must be skilled in the art of teaching.

Iowa: First-class certificate, good for two years, a State certificate, or a life diploma.

It is unquestionably true that a supervisor should be as well and as highly educated as the better teachers he supervises. He should be a man of broad and generous culture, a lover of good books, versed in the best literature of the day, one whose presence is an influence for good, and whose words are an inspiration.

the State of Maine. The whole matter turns upon the simple point that we are alarmingly wasteful in our expenditure of school money.

Personally I am in favor of local communities being responsible for providing school buildings. I think two-thirds of the funds required for the maintenance of the common schools should be furnished by the State, and that the other third should be raised by local taxation; that the State should examine all teachers and issue all licenses to teach; that towns thus receiving State aid must employ teachers who hold such certificates. The State should inspect the school accounts of the towns receiving State aid.

The subcommittee deems it advisable, now that the whole ground has been covered, to restate the fundamental propositions that have been urged in this report. These all start from the one central postulate that a provision of funds sufficient for their adequate support is essential to the existence and life of good schools. The threefold division of the subject will be preserved in the summary.

I. REVENUE.

1. The great resource of the public schools is, and must continue to be, some form or forms of public taxation.

2. Such areas or units of taxation should be created, or continued if already in existence, as will fully develop the sound American principle that the whole wealth of the State shall be made available for educating all the youth of the State.

3. To accomplish this end, resort must be had to the larger units of taxation, especially where population is sparse and wealth meager. The following recommendations must be specifically urged: (1) A liberal provision of funds from the State treasury; (2) a county tax in at least all the county-system States; (3) a town or township tax in the States where this civil division exists; (4) taxes in special districts; that is, in cities and villages. The school district, in the commonly accepted sense of that term, is not a desirable taxing unit, but quite the contrary, and should be abolished as such unit.

II. DISTRIBUTION.

1. Funds raised by the large political or social units for general school purposes should be distributed in such a way as to bring the rich and the strong to the help of the poor and the weak.

2. Such rules of distribution should be adopted as will accomplish this end. In order to do this, distribution must be based, to a certain extent at least, upon fixed or arbitrary units; that is, so much money must be given to the school or to the teacher.

3. The large taxing units should render assistance to the small ones only upon the condition that the small ones first do something for themselves.

III. ORGANIZATION.

1. In the States where the town or mixed system of local government exists, the town or township school system should, as far as practicable, be substituted for the district system; in the county-system States the county-school system is the natural alternative to the district system.

2. In those parts of the country where existing physical and social conditions render it practicable, there should be such a consolidation of rural schools as will diminish the existing number of schools, schoolhouses, and teachers, and bring together, at advantageous points, the pupils who are now divided and scattered among the isolated schools of the township or other similar districts.

3. There is urgent need of lengthening materially the time that the country schools, on the average, are in session each year. The ideal should be a minimum school year in every State of at least one hundred and sixty or one hundred and eighty days.

The subcommittee does not expect to see, and does not desire to see, the school systems of the country all brought to one uniform pattern. It is too well aware of the great diversity of conditions that exist to think such a thing is possible. Even more, a certain variety, and so conflict, of systems is conducive to life, activity, and improvement. Neither is the subcommittee under any illusions as to what is possible, or probable, in a field of education so vast as that offered by the United States, with the great number of authorities, State and local. At the same time there are certain general laws governing successful school systems and schools that can not be ignored. Some of the principal of these laws have been set forth above; and it is believed that their general recognition will be followed by a marked improvement of the common schools, and so of the popular education of the country.

Some persons may ask, "How shall the principles laid down in this report be made practical?" "How shall they be established in communities or States where they do not exist, or exist only in part?" To these questions only a general answer is needed. The State legislature, the lawmaking authority, is the only source of power in relation to education, as well as in relation to all other branches of the State government. Accordingly, if the school law is defective and weak, the legislature must be called upon to repair and strengthen it. No progress can be made without an efficient law and efficient school authorities.

But how shall the legislature be induced to act in the premises? In precisely the same way that it is induced to act in other matters. Facts, arguments, persuasion, must be addressed to the members of the legislature. Above all it is important that the public mind shall be informed as fully as possible upon all branches of the subject. If the people generally knew how much better schools they might have than those that they do now have, and for no more cost, it is impossible to believe that they would not bestir themselves to effect reforms. The subcommittee marks out what it believes to be broad lines of educational progress. It enforces its views, as far as possible, with appropriate arguments. But it must necessarily leave the application of these views and arguments to the exigencies existing in particular communities or States to such persons, belonging to these communities or States, as are interested in the subject and are familiar with all the local facts and conditions.

B. A. HINSDALE, *Chairman.*
W. S. SUTTON.
S. T. BLACK.

REPORT OF THE SUBCOMMITTEE ON SUPERVISION.

The subcommittee on supervision of rural schools has taken into careful consideration the various topics submitted for investigation. Its inquiries have extended into all the States and Territories except Indian Territory and Alaska, and the facts are based on returns more or less full from all parts of the country.

Professional supervision is to-day regarded as an essential factor in our school system. It has been observed that the schools that are closely supervised by men who thoroughly know their business at once respond to the influence of this supervision. Expert supervision has resulted in systematic, orderly, and well-directed instruction. It is a matter of remark that the most competent superintendents have the best schools, and that cities noted for their excellence in school work have attained this preeminence through the medium of intelligent supervision. This is also true of those counties which have come under the same influence.

"There is no other agency in our school system that has done so much for the improvement of our schools in organization, and in methods of instruction and discipline, as the superintendency."

The attention of the profession, however, has been mainly directed toward

expert supervisions in city schools, and but little heed has been paid to the demand for such work in rural districts. It is quite time that our inquiries should be directed toward the character of the supervision demanded by the country school. If supervision through a competent superintendent is a good thing for city schools, there is every reason why it would be a good thing for rural schools.

STATE SUPERINTENDENT.

Although the State superintendent stands at the head of the public-school system of the State, his work is more closely related to rural than to city schools. As this report has reference only to the conditions of rural schools, your subcommittee will consider the duties of this officer as bearing upon that part alone of the general school system. No officer connected with the administration of State affairs requires higher or more essential qualifications than that of superintendent of public instruction. He should be a man of high moral character, well acquainted with approved methods and with the history and condition of education in his State. He should be in close touch with the educational spirit of the times, and should be one whom the profession regards as authority in all that constitutes excellence in school matters. It is also agreed that he should be an experienced teacher, of broad and thorough scholarship, and a good public speaker. With these qualifications there should be combined a large share of good common sense, and sufficient executive ability to manage the details of his office.

The legal term of office in Massachusetts and Rhode Island is one year. In Connecticut it is at the pleasure of the State board. In twenty States the term of office is two years; in four States, three years; in seventeen States, four years; but in no State does it exceed four years. The average length of term of the State superintendent is two years and ten months. The lowest salary paid is $1,000 and the highest $5,000 per year. The average salary is $2,475 per year. In answer to the question as to how much time the State superintendent devotes to supervision of schools, we had definite answers from thirty-seven States, in which we find that nineteen of these superintendents devote more than half of their time to visiting schools and traveling in the interest of education, and eighteen devote less than half their time. Quite a number of the State superintendents report that they divide their time equally between the office work and supervision. In only a few of the States does the State superintendent exercise no supervision, and in several the supervision is carried on through deputies or agents.

The State superintendent under present arrangements has but little time for personal inspection of school work. The superintendents in fourteen States visit each county once a year and in eight States once every two years. From the other States no definite information could be obtained. Many superintendents say, as often as practicable; in some instances, not at all. Our information is to the effect that most of the State superintendents devote as much time to supervision as they can spare, but that it is generally considered secondary to work of a clerical nature. There are undoubtedly in some States sections which have never been visited by the State superintendent or his deputy.

By some means the influence of the State superintendent should be extended until it reaches every rural school in the State. In all possible ways the office should be made useful to the teachers and school officers. The rural schools need this stimulating, helpful influence more even than those of the city. While in most States the office has but little more than advisory powers, yet, through lectures at associations and through the inspection of institutes, the State superintendent ought to be able to convince the teachers of rural schools that he is in close sympathy with their work.

The work of the State superintendent ought to be made more effective by so increasing his clerical force as to enable him to spend more time in direct contact

with the schools and school officials of the State. The careful compilation of statistics is very important, but it can be intrusted to a skillful statistician, while much of the routine work of the office can be well done by clerks. The higher and by far the more important work of directing educational movements, of instructing the people, and of creating public opinion and arousing public interest devolves upon the State superintendent. There is a general demand for more assistance in his office, longer tenure of service, and more liberal financial support. His work should be so related to that of the superintendents in the various subdivisions of the State for school purposes that the whole may be properly articulated, and the county or town superintendents be under his direction and control. He should come in frequent contact with them by conventions held for the purpose of instructing them in their particular duties, and should send them such circulars and letters as may be necessary to aid and direct them in their work.

The State superintendent should have the power to withhold the State appropriation from all counties or school districts not complying with the law in every particular, because he would then hold the key to the situation and could enforce his orders.

The main duties of the State superintendent are not only to organize and direct educational influence and laws already existing, but also to go among the people in the spirit of Horace Mann, and, by public addresses, by the liberal use of the press, and by securing the assistance of the leading men of the State, to arouse and keep alive an interest in the cause of popular education. In connection with the rural schools especially the State superintendent not only has great possibilities for a wise supervisory influence, but also great opportunities to arouse and instruct the people.

In a majority of the States the most needful legislation is that which bears upon the organization and maintenance of rural schools, and a supply of competent teachers for the same. The State superintendent, therefore, should be a man able to secure the cooperation of the legislature for the enactment of proper statutes. This can be done only by one who sees clearly the great needs of the school system, and who is able to go before the people and the legislature and unite all influences to obtain the necessary legislation. While putting into this high office any person solely through his political affiliations is to be deprecated, the State superintendent should be a man who knows how to approach the leaders of all parties and convince them of the justice and soundness of his plans, viewed from the high vantage ground of the general good.

COUNTY, TOWNSHIP, OR DISTRICT SUPERINTENDENT.

A still more important question opened for discussion is the character and degree of supervision below that of the State superintendent.[1] Thirty-eight States, mainly in the South and West, have county superintendents, whose duty it is to visit the schools and exercise the duties usually belonging to their office. The New England States generally have what is known as township or district supervision, which arises in large part from their political organization. In New England the town is the dominant political unit, while in the South and West it is the county. The simplicity and effectiveness of supervision are promoted when the units of political organization and of school administration are identical. This condition has its limitations, however, in the amount of territory to be covered and in the density of population, which is a varying quantity. The main point is to bring every rural school of the country as far as possible under the watchful care of a competent supervising officer. Responsibility is a strong

[1] In this report the term "supervisor" is used to include also county superintendent, commissioner, or any other term by which the supervising officer of a county or supervisory district is usually designated.

stimulant. It is one of the weak points in our present system that too often the rural school-teacher is responsible to no one.

In regard to the operation of the two principal methods of supervision, there is no reason why any section should abandon the practice which has been found best adapted to its peculiar conditions. It must be conceded, however, that a single township, containing on an average ten or twelve schools, is too small a territory to engage profitably the entire attention of one person. In such a case one of two things must necessarily happen: Either the schools are supervised to the point of interference, or the supervision becomes uncertain, feeble, and unsatisfactory. In a general way, the rural township is too small a supervisory unit. Wherever it has been tried the supervisor has generally had some other business to attend to, and thus his work has been found wanting in those results which are most desirable. In order that the work of overseeing and directing may be effective, it must engage the entire time and the best thought of the supervisory officer.

A proper remedy for this is the combination of towns for supervisory purposes. Three, four, or five towns could be united in one supervisory district until a sufficient number of schools have been secured to engage the entire attention of one good man. The burden of his salary could be borne by these towns in the proportion of the number of schools they contribute to his work. This plan is in operation in Massachusetts, and has been satisfactory. A complete exposition of the Massachusetts plan of supervision of township schools is found in A. W. Edson's monograph, "Supervision of schools in Massachusetts." (Boston, 1895).

In that State 253 of the towns are supervised by 155 supervisors. While some of the large towns can alone support a supervisor, several of the smaller ones must unite to secure the services of an efficient officer. In addition to what the towns do for themselves, the State grants to those of low valuation, when they combine into a supervisory district, the sum of $750 to pay for a supervisor. These towns, however, are required to raise an additional sum equal to that furnished by the State, thus insuring a sufficient sum for the employment of an expert schoolman. By these means 93 per cent of the children of Massachusetts have been brought under close supervision. The salary paid to a supervisor is at least $1,500 a year, and he is enabled to devote all his time to the work and to inspect each school once a month. It is true that there are still about one hundred towns in Massachusetts without supervision, yet the feasibility of cooperative supervision with aid from the State is proven beyond all doubt.

"The State aid to a district amounts at present to $1,250—$750 toward the superintendent's salary and $500 toward the salaries of the teachers. The remainder of the superintendent's salary, $750, must be raised by the towns of the district. They are at liberty, of course, to raise more than $750 for the purpose, if they desire to do so." (Massachusetts State Report, 1895.)

What has been said regarding the combination of towns for supervisory purposes can be repeated with equal emphasis as to other small divisions of territory termed "school districts." The same principle applies here as elsewhere, that the interests of the schools included in a given territory should be sufficient to warrant the employment of a thoroughly competent person at such a salary as would justify devoting his entire time to his work. After all has been done, there will still be vast sections of country, especially in the West and Southwest, without any means of efficient supervision. No present remedy can be devised to aid them. It can be safely left for the several States, as population increases, to look after the interests of the schools in the light of the experience of older communities about them.

The worth of the county superintendency is acknowledged, but in many cases the county is too large an area and contains too many teachers for one man to properly supervise. The county is as much too large a unit for supervisory purposes as the township is too small. This remark, however, does not apply to every

county nor to any one State. In counties where the number of teachers is too large for one man to supervise the county superintendent should have one or more assistants or deputies to aid him in his work. They should be directly responsible to him for the kind and character of their work, and should be charged solely with supervisory duties. The importance of having one superintendent for the county or district to whom other supervisors are responsible must be emphasized, as it would be an error and a fruitful source of strife if in any territory there should be two or more supervisors having concurrent jurisdiction.

THE COUNTY UNIT.

Since this report is a symposium of suggestions for supervising rural schools, it may not be amiss to discuss a plan of supervisory organization that has found favor in some few counties that contain large cities as well as a rural population. We mention it here because it has valuable features for supervising the rural schools. There is but one school board for the entire county. One set of men legislates for the whole area, and it is their duty to relate the urban and suburban and rural schools into a sympathetic system. This is based upon the idea that every city is bound to respect the people that immediately environ it. It is to the interest of a large city to have good roads leading to it, good crops in the fields around it, and good schools to which the farmers may send their children.

With this as a foundation principle there is but one school fund for the entire county, raised by taxation upon all property in the county, whether it be in or out of the city. This makes the general school fund, which is distributed upon the basis of school population and according to the needs of the city wards and the rural communities. The same qualification for teachers is required whether they teach in a city graded school or in a country ungraded school, and the same salary is paid to them and in the same way and for just as long a term. In this system one superintendent is in charge of the whole area. He looks after a city graded school one day and the next day may be 20 miles away inspecting a country school. Expert supervision by a superintendent and his assistants is thus extended into the rural districts, and both city and country school receive the benefit of what there may be in each that is of real value.

Upon this plan, as a matter of course, a large portion of the school fund raised by taxation on city property is annually distributed to the country schools. The city is really made to assist in supporting the rural schools around it. And who shall say it is not a good thing for the city to do, especially in agricultural sections, in which the education, liberal and special, of the farmer's child is the probable salvation of the farming interests of the country? We should not lose sight of the truth that the farmer's child is to be made a useful citizen, not only content to stay in the home in which he was born and reared, if that is best, but fitted to fill honorably any station in life to which he may be called. To do this he must have all the opportunities of education and culture that the city affords. This can be brought about in no other way than at the city's expense, for wealth is massed in our populous centers. The expert supervision, the well-trained teacher, the long term, the modern text-book, the good schoolhouse, can be placed at the farmer's door by the agencies of the neighboring city, that owes him this and much more (Appendix D).

TRAINED TEACHERS NEEDED IN COUNTRY SCHOOLS.

Supervision is one of the vital needs of the rural schools, since most of their teachers are inexperienced. The number of normal-school graduates in rural schools is lamentably small. The reason is that the normal-school graduate can obtain a better salary by teaching in a larger field. The demand for this class of teachers makes their salaries so high that the country schools can not afford to employ them. As soon as teachers become proficient by reason of experience

acquired in rural schools, the probabilities are that they will be induced to seek better positions in cities where their experience and abilities will command higher salaries.

Add to this the other fact that many young men begin to teach as a stepping-stone to some other profession, and while they are teaching a country school are studying law or medicine, and their hearts are with that rather than with teaching; and also add that many young girls teach until they marry, or as long as they are compelled to teach, and no longer; that they have no real love for their work and no wish to stay in it, and we see how the problems multiply.

Rural schools suffer from lack of trained teachers. In them, as a general thing, are young graduates from the village high school, or some favorite among neighborhood families, or a type of ancient teacher whose placid life is not disturbed by the vexing problems of his profession. This raw material must be developed, made shapely, orderly, and systematic, if time is to be saved to the children, and schools properly supported. A bright and live supervisor will bring order out of confusion, harmony out of discord, and will give life and beauty to that which before was inert and ungainly.

Teaching is a great art, based on a profound science. The supervisor is the expert who has given this art and science his careful attention and whose business it is both to know how to teach and to show others the way of teaching. He can in some measure compensate for the lack of skilled work in the school by closely supervising and guiding inexperienced teachers and showing them what to do. An expert is one who possesses skill gained by practice. A supervisor who claims to be an expert should have experimental knowledge of "the how to teach." He is supposed to have given careful attention to those things which characterize a good school. Not only must he know how to teach, but he must know how to instruct others in the art and science of teaching. He must be a skilled teacher of teachers. Without this directing spirit, schools must necessarily suffer until teachers happen upon some better way. It is a great misfortune for schools to wait for wisdom in teaching until the many mistakes of teachers have pointed out better methods. The presence of skilled supervision has been the salvation of many schools.

It is one province of supervision in the country school to bring teachers into contact with each other, to illustrate better ways of teaching, to break up the isolation and monotony of rural school life, and to take to the doors and homes of people and teachers alike the life and freshness which have been the result of research and study on the part of the best minds in the profession. The province of supervision in rural schools falls far short of its legitimate purposes when it begins and ends in the schoolroom.

This point is not sufficiently well appreciated by those who have the oversight and care of schools scattered over a large tract of territory. Country schools have an environment of their own which should neither be forgotten nor ignored. The best supervisory work is that which brings into the rural school everything in farm and rural life which is strong and pure and wholesome. It is possible for the supervising officer so to exert his influence as to give grace and dignity to each individual school and make it the rallying point for every good influence, a blessing to the entire community in which it is situated.

Attention is here called to the fact that in general but little care is taken in the selection of officers chosen to look after the interests of the rural schools. In the majority of States the county superintendents are elected by the people of the county without any regard to the preparation or qualifications they may have for the work. Very few States require the superintendents to have any special qualifications, and in many instances supervisors are put in charge of teachers who know more about teaching than they do, and are required to hold examinations that they themselves could not pass. Add to this the fact that the superintend-

ents are generally paid very small salaries (average, $828 for the whole country) or a meager per diem, and that many engage in other business and regard supervision of schools as an incidental matter, and it becomes apparent that professional supervision is too often the exception rather than the rule.

WORK OF SUPERVISORS.

We need everywhere trained superintendents of schools. "Supervision of schools should rank next in importance to the instruction in schools; indeed, so necessary to successful instruction is competent supervision that the two should receive together the watchful oversight of the State" (New Jersey State Report, 1894). Supervisors should know as much of teaching as the teachers under them, and should be able instinctively to distinguish good teachers by their manners, dress, speech, disposition, and character. The best work of a supervisor is his skill in selecting teachers. Not by the results of examination alone, for some learned people make poor instructors; not by yielding to the pressure of family or political influence, for this will ruin any system of schools; not by selecting his own friends or favorites, for this is unworthy of his office; but by following the knowledge that comes to him through study, by long experience, by careful observation, and by conscientious conviction, which enables him to know a teacher when he meets one, though he may not be able to tell why.

Teaching is a matter of both disposition and knowledge. The former can not be examined, but it ought to be recognized; careful supervision will aid in developing it. Skill in doing this is an essential characteristic of a good supervising officer, especially in connection with rural schools. If the cry is raised (and it is) that there is not enough money to pay for professional supervision, the reply is that it would be wiser to have fewer teachers in order that those employed might be better qualified. A supervisor who is an expert can so arrange and organize the system that a less number of teachers can do the work and do it better, because each one is thoroughly competent. "A good superintendent earns many times his salary; a poor superintendent is too dear at any price. The work of supervision may be unsatisfactory either because the number of schools is too large for the oversight of one person, or because the supervising officer lacks the talent for molding, inspiring, and directing the work of others" (Pennsylvania State Report, 1895). Underpaid supervision is often unskilled and inefficient, and against this we raise our decided protest. Such supervision is of no value whatever to the schools—a penny-wise policy that economizes in the wrong place. A supervisor should have no other business than to care for the schools. He should not be a merchant, nor a lawyer, nor a farmer, nor an active teacher. His business should be to supervise the schools of his county, or township, or district, or whatever his area be called.

With a given sum of money for school purposes, to devote a part of it to skilled supervision will bring more children under enrollment, better teachers in the community, better instruction in the schools, and more satisfaction to the people, than if all the money were spent in paying the salaries of teachers.

In twenty-eight States the supervisors are required by law to visit each school twice a year, in the other States they are allowed to visit the schools as often as practicable. In one or two States the supervisors visit the schools very seldom. The length of time the supervisor spends in each school varies from fifteen minutes to one-half day. The time seems to depend very largely upon circumstances, the number of pupils, the character of the teacher, the efficiency, and the pay of the supervisor. A skilled supervisor inspecting an intelligent teacher can do more service in fifteen minutes than an unskilled supervisor visiting a poor teacher can do in a whole day. The average time spent in the ordinary rural school by the school supervisor is about one hour every year.

In twelve States the supervisors devote all their time to the work. In these

States the average salary is $1,002 a year. In fourteen States the supervisors devote only a part of their time to supervision, with an average annual salary of $408. Sixteen States report that in some counties the supervisors devote all their time to supervision, while in other counties the supervisors devote but a small part of their time to that work. In these States the salaries paid supervisors vary from $100 to $2,000 or $3,000 a year. Where good salaries are paid they devote all their time to supervision. Where small salaries are paid they devote but little time to this special work. All States have some supervision, though it varies greatly in amount and in efficiency.

In many sections of the country a supervisor not capable of suggesting to teachers better methods of teaching and not able to detect false methods pays only a perfunctory visit to the schools. He merely sees whether the building is clean, whether the children look bright and interesting, whether the enrollment is good, such facts as would be noticed by any person of ordinary common sense. Too often the contact of the average supervisor and the teacher of the rural schools is nothing more than a mechanical business performance, with such elements of aid and encouragement as any intelligent visitor may give the school. Although this is not without advantage, it falls far below the standard of professional supervision.

How many teachers a supervisor can direct can not be discussed except in a general way. Schools are more widely separated in some localities than in others, roads are better, teachers are better, and supervisors vary greatly in the rapidity with which they work. As a general rule, however, every rural school ought to be visited at least once in two months. Supervision can not be called close that does any less than that, and it would be better if the schools could be visited once every month.

No accurate information can be gained concerning the conditions of the school, nor can the proper influence be exerted over teacher and pupils, unless the supervisor has time at his disposal to make a reasonably thorough examination of the school and its surroundings. Sometimes, with an inexperienced teacher, he may find it necessary to spend the entire day in the school, while in other cases he may be able to visit two or more schools in one day. The point is that he must not feel compelled to shorten his visit, or to leave his work half done, in order to meet other engagements. To make his visits effective in the highest degree requires time and patience. The length of his visit must depend upon the necessities of the school, and of these he must be his own judge. An ideal system of supervision would give one supervisor from fifty to seventy-five teachers to supervise. Where the number of teachers is greater some will be neglected, for a supervisor generally has many interruptions in his work, such as rainy days, holidays, and the demand upon his time for office work, board meetings, committee meetings, public addresses, etc., so that it is impossible to put in every day in supervision. Allowance must be made for other important duties.

Attention is also called to the power which the supervisor can exert through rightly conducted teachers' meetings, institutes, associations, and round tables. Here he may meet the teachers under his direction, and make use of the information which he has gathered in visiting their schools. From free and open discussions by the teachers he will get an insight into their habits of thought and their methods of expression. Such meetings help break up the unsocial character of rural teachers by bringing them into contact, so that each learns something from the experience of all the others. In this way teachers and supervisors become better acquainted, gather fresh courage and new inspiration, and go home feeling that they have much in common, and that, if they will, they can in many ways be mutually helpful. The most deadening influence about the country school is its isolation. Nothing is more potent in overcoming this than frequent gatherings in which teachers, school officers, and parents freely discuss matters of common interest. To encourage such meetings is one of the duties incumbent upon

the supervisor. Without being too prominent, he may still be the inspiring spirit, guiding, directing, and stimulating the tone and energies of all who participate in the proceedings (Appendix P).

LEGAL REQUIREMENTS AND QUALIFICATIONS.

The necessity of establishing some qualifications to be required of those who are to occupy the position of supervising officer is emphatically insisted upon.

"If it is desirable to insist upon a certain degree of qualification for a school-teacher in the humblest district of the State (this proposition has passed beyond the realm of discussion), it would seem that there is no question that the superior officer clothed by statute with such extended powers as a school commissioner ought to be a person possessing some fixed qualification for the performance of the duties of his office. The schools of the State will never reach that degree of efficiency which the State has a right to demand, and which is expected from the generous provision made for their support by the people, until this evil is corrected. Some standard of qualification should be insisted upon, and the power of removal in case of the election of a person not possessing these qualifications should be vested in the State superintendent." (New York State Report, 1895.)

In only seventeen States are there any qualifications, beyond that of being a resident and a voter. In some States a first-grade license is required, in others a normal or university course, and again in others he must be an experienced teacher. In a majority of the States, however, the electors are allowed to choose any person without regard to educational qualifications.

In answer to circulars of inquiry the following information was obtained regarding supervisors:

Wisconsin: By the law of 1895, must hold a university, normal, State, or special superintendent certificate.

New York: No standard of qualification.

Pennsylvania: Must hold a college diploma, or a State or local certificate; must have at least three years' experience in teaching.

Michigan: Must be a graduate of a reputable college, university, or State normal college, or must hold a State or first-grade certificate.

Mississippi: Must hold a first-grade certificate.

Texas: Must be a person of educational attainments and hold a first-grade teacher's certificate.

Tennessee: Can be appointed only from applicants who pass an examination on questions sent out by State board.

Georgia: Must pass a satisfactory examination.

Louisiana: Must have a common-school education.

Montana: Must hold a first-grade certificate and have one year's experience as teacher.

South Carolina: Must be able to conduct a teachers' institute.

Kentucky: Must be able to obtain a first-class teacher's certificate, hold a State diploma, or State certificate.

Arkansas: Must have a first-grade certificate.

Maryland: The county school board may require applicants to be examined by the State superintendent.

Utah: Must have a valid certificate not lower than the grammar grade.

West Virginia: Must be skilled in the art of teaching.

Iowa: First-class certificate, good for two years, a State certificate, or a life diploma.

It is unquestionably true that a supervisor should be as well and as highly educated as the better teachers he supervises. He should be a man of broad and generous culture, a lover of good books, versed in the best literature of the day, one whose presence is an influence for good, and whose words are an inspiration.

roundings of the schools of which he is to take charge. If the new departure ich seems to be at hand in rural-school education is to be a success, it must carefully conducted in reference to those environments which are peculiar to h section. The supervisor who is to have a controlling influence in choice of t-books, in courses of study, in the selection and use of libraries, should be oroughly conversant with the physical characteristics of his district, with the erests of the people, with their sources of wealth and living, and with the home e of the children (Appendix O). Whether it be a mining or a grazing region, hether agriculture or horticulture predominates as an interest, he should make imself at home in that domain of science or knowledge which will increase his efulness as a school officer.

THE HOME AND THE SCHOOL.

The parents of children need instruction as well as the children themselves. The home influence and the school influence should be harmonious, or confusion and uncertainty will arise in the child's mind as to what he should do. The people must be reminded that the school is an integral part of the community, and not a separate affair which the law compels them to support and which takes their children away when their assistance on the farm is most valuable (Appendix O).

In establishing the true relations between the home and the school, between the necessities of physical and those of intellectual education, the supervisor of rural schools finds an unlimited field of usefulness. In rural districts parents are often ignorant of the advancement education has made since the days when they went to school, and they are often too ready to criticise anything new. The supervisor must gain their confidence, so that they will yield their ideas to his and allow the teacher in their school to follow his directions without any hindrance from them.

The supervisor can exert a wonderful influence in bringing the fireside to the support of the teacher. To do this he must be able to educate the people concerning their relation to the school, as to sending the children regularly, as to providing necessary material, such as books, etc., as to allowing every teacher to pursue those methods of teaching which his skill and experience suggest as best suited to the wants of the school. At meetings of agricultural clubs, at town rallies, at educational "barbecues," at commencements, at spring festivals, at farmers' institutes, he should embrace every opportunity of saying a word for the schools, in order to arouse the people and interest them in the whole system of education. The columns of the country paper afford the supervisor a very ready means of reaching the people. Almost every farmer takes the county paper, which, coming weekly to his fireside, gives the news of the outside world and the doings of his neighbors. School news is an important item and should never be omitted. Every week the paper should contain something of educational interest from the pen of the supervisor, though not always over his signature—suggestions for improvement, statistics of enrollment and attendance, new and better ways of teaching, plans for schoolhouse construction and decoration. The press is valuable to every teacher and helpful to the system of education by bringing farmers into sympathy with the great educational movements of the world. The press gives a larger audience, though it enforces a shorter address. But a little every week, full of variety and interest, will eventually build up a healthy sentiment in the county and educate parents as well as children.

The supervisor should have a direct or indirect control of the selection of teachers. The crisis in the history of schools is when teachers are to be chosen. No one is so well qualified to choose them wisely as a faithful supervisor, and no one is more likely to do so conscientiously, since he knows the value of efficient teach-

To require him to be in every case a graduate of some higher school would be unreasonable, perhaps, but he should be a friend of higher education in every sense of the word. He must for a long time continue to be one from whom will come the influence which will lead the pupils in the rural district to strive for the highest education possible under the circumstances. His influence should be given to the establishment of rural or township high schools wherever the population will permit it. These schools should include in their courses whatever is required on the one hand for entrance to the school of the next higher grade, or, on the other, those studies a knowledge of which can be made so to change life on the farm, in its various forms, that it will become more attractive and more profitable. In the establishment and conduct of such schools the influence of the supervisor should be a very prominent factor.

A supervisor should have a thorough knowledge of school work. He should know what a teacher ought to do in managing a class of pupils of any age on any subject. This is one of the things he is paid to know. He should be an expert to whom teachers may go for advice and direction. If the advice is good and the direction wise, teachers will have confidence in the administration of the schools, and rely more and more upon the supervisor. The system is thus reduced to uniformity and becomes a source of strength. The supervisor should be able to direct teachers in their professional reading, and select wisely a library of teachers' books, and place them where they are most needed. He should know about school periodicals and be able to form his teachers into reading clubs and circles, and direct their studies. He should be able to arrange teachers' meetings so that time will not be wasted, and that teachers will come with pleasure and stay with profit. He ought to be able to aid in selecting a library suited to the wants and tastes of an agricultural community (Appendix L). In school extension he should be a leader, for he can thus make his influence felt in every part of his territory. In directing the home reading of the pupils and the people he may, if he will, find an immense field of usefulness. He can thus create and foster an interest in the welfare of the farm and the home as adjuncts to the rural schools.

He can understand and sympathize with teachers better if he has an experimental knowledge of their work. No supervisor is so good as he who climbed from the lowest rounds and knows all the steps. That this is indispensable we are not prepared to state. There are some very excellent supervisors who have but little experince in teaching, but who have seen enough and studied enough to know how it ought to be done. Experience would have been helpful, however, in understanding the limitations of their work.

First and foremost, a supervisor should be able to instruct his teachers in the methods of organization and management of schools. This is particularly the case in rural schools, where so few teachers have acquired skill in teaching. But instruction with a teacher is like instruction with a child. There must be an awakening, an arousing, a hungering after instruction. The conditions of "being filled" are that we must "hunger and thirst." The supervisor must inspire his teachers with a desire for better things. He should lead them to see that time is precious, and that the children in school this year may be on the farms next year and no more in school forever. They must know what to do and do it. The supervisor should be a source of inspiration. His corps of teachers must be alive and eager and studious. The thing most to be abhorred in school work is the teacher dead to advancement in professional studies. The supervisor must rouse teachers to work out for themselves plans and methods for building up their schools, and must set forth the principles which should control them in their work.

The county superintendent, or the supervisor of schools in any rural community, should have had recent experience in the schools which he is to supervise. In cases where this is not possible he should make a careful study of the peculiar

surroundings of the schools of which he is to take charge. If the new departure which seems to be at hand in rural-school education is to be a success, it must be carefully conducted in reference to those environments which are peculiar to each section. The supervisor who is to have a controlling influence in choice of text-books, in courses of study, in the selection and use of libraries, should be thoroughly conversant with the physical characteristics of his district, with the interests of the people, with their sources of wealth and living, and with the home life of the children (Appendix O). Whether it be a mining or a grazing region, whether agriculture or horticulture predominates as an interest, he should make himself at home in that domain of science or knowledge which will increase his usefulness as a school officer.

THE HOME AND THE SCHOOL.

The parents of children need instruction as well as the children themselves. The home influence and the school influence should be harmonious, or confusion and uncertainty will arise in the child's mind as to what he should do. The people must be reminded that the school is an integral part of the community, and not a separate affair which the law compels them to support and which takes their children away when their assistance on the farm is most valuable (Appendix O).

In establishing the true relations between the home and the school, between the necessities of physical and those of intellectual education, the supervisor of rural schools finds an unlimited field of usefulness. In rural districts parents are often ignorant of the advancement education has made since the days when they went to school, and they are often too ready to criticise anything new. The supervisor must gain their confidence, so that they will yield their ideas to his and allow the teacher in their school to follow his directions without any hindrance from them.

The supervisor can exert a wonderful influence in bringing the fireside to the support of the teacher. To do this he must be able to educate the people concerning their relation to the school, as to sending the children regularly, as to providing necessary material, such as books, etc., as to allowing every teacher to pursue those methods of teaching which his skill and experience suggest as best suited to the wants of the school. At meetings of agricultural clubs, at town rallies, at educational "barbecues," at commencements, at spring festivals, at farmers' institutes, he should embrace every opportunity of saying a word for the schools, in order to arouse the people and interest them in the whole system of education. The columns of the country paper afford the supervisor a very ready means of reaching the people. Almost every farmer takes the county paper, which, coming weekly to his fireside, gives the news of the outside world and the doings of his neighbors. School news is an important item and should never be omitted. Every week the paper should contain something of educational interest from the pen of the supervisor, though not always over his signature—suggestions for improvement, statistics of enrollment and attendance, new and better ways of teaching, plans for schoolhouse construction and decoration. The press is valuable to every teacher and helpful to the system of education by bringing farmers into sympathy with the great educational movements of the world. The press gives a larger audience, though it enforces a shorter address. But a little every week, full of variety and interest, will eventually build up a healthy sentiment in the county and educate parents as well as children.

The supervisor should have a direct or indirect control of the selection of teachers. The crisis in the history of schools is when teachers are to be chosen. No one is so well qualified to choose them wisely as a faithful supervisor, and no one is more likely to do so conscientiously, since he knows the value of efficient teach-

To require him to be in every case a graduate of some higher school would be unreasonable, perhaps, but he should be a friend of higher education in every sense of the word. He must for a long time continue to be one from whom will come the influence which will lead the pupils in the rural district to strive for the highest education possible under the circumstances. His influence should be given to the establishment of rural or township high schools wherever the population will permit it. These schools should include in their courses whatever is required on the one hand for entrance to the school of the next higher grade, or, on the other, those studies a knowledge of which can be made so to change life on the farm, in its various forms, that it will become more attractive and more profitable. In the establishment and conduct of such schools the influence of the supervisor should be a very prominent factor.

A supervisor should have a thorough knowledge of school work. He should know what a teacher ought to do in managing a class of pupils of any age on any subject. This is one of the things he is paid to know. He should be an expert to whom teachers may go for advice and direction. If the advice is good and the direction wise, teachers will have confidence in the administration of the schools, and rely more and more upon the supervisor. The system is thus reduced to uniformity and becomes a source of strength. The supervisor should be able to direct teachers in their professional reading, and select wisely a library of teachers' books, and place them where they are most needed. He should know about school periodicals and be able to form his teachers into reading clubs and circles, and direct their studies. He should be able to arrange teachers' meetings so that time will not be wasted, and that teachers will come with pleasure and stay with profit. He ought to be able to aid in selecting a library suited to the wants and tastes of an agricultural community (Appendix L). In school extension he should be a leader, for he can thus make his influence felt in every part of his territory. In directing the home reading of the pupils and the people he may, if he will, find an immense field of usefulness. He can thus create and foster an interest in the welfare of the farm and the home as adjuncts to the rural schools.

He can understand and sympathize with teachers better if he has an experimental knowledge of their work. No supervisor is so good as he who climbed from the lowest rounds and knows all the steps. That this is indispensable we are not prepared to state. There are some very excellent supervisors who have but little experince in teaching, but who have seen enough and studied enough to know how it ought to be done. Experience would have been helpful, however, in understanding the limitations of their work.

First and foremost, a supervisor should be able to instruct his teachers in the methods of organization and management of schools. This is particularly the case in rural schools, where so few teachers have acquired skill in teaching. But instruction with a teacher is like instruction with a child. There must be an awakening, an arousing, a hungering after instruction. The conditions of "being filled" are that we must "hunger and thirst." The supervisor must inspire his teachers with a desire for better things. He should lead them to see that time is precious, and that the children in school this year may be on the farms next year and no more in school forever. They must know what to do and do it. The supervisor should be a source of inspiration. His corps of teachers must be alive and eager and studious. The thing most to be abhorred in school work is the teacher dead to advancement in professional studies. The supervisor must rouse teachers to work out for themselves plans and methods for building up their schools, and must set forth the principles which should control them in their work.

The county superintendent, or the supervisor of schools in any rural community, should have had recent experience in the schools which he is to supervise. In cases where this is not possible he should make a careful study of the peculiar

surroundings of the schools of which he is to take charge. If the new departure which seems to be at hand in rural-school education is to be a success, it must be carefully conducted in reference to those environments which are peculiar to each section. The supervisor who is to have a controlling influence in choice of text-books, in courses of study, in the selection and use of libraries, should be thoroughly conversant with the physical characteristics of his district, with the interests of the people, with their sources of wealth and living, and with the home life of the children (Appendix O). Whether it be a mining or a grazing region, whether agriculture or horticulture predominates as an interest, he should make himself at home in that domain of science or knowledge which will increase his usefulness as a school officer.

THE HOME AND THE SCHOOL.

The parents of children need instruction as well as the children themselves. The home influence and the school influence should be harmonious, or confusion and uncertainty will arise in the child's mind as to what he should do. The people must be reminded that the school is an integral part of the community, and not a separate affair which the law compels them to support and which takes their children away when their assistance on the farm is most valuable (Appendix O).

In establishing the true relations between the home and the school, between the necessities of physical and those of intellectual education, the supervisor of rural schools finds an unlimited field of usefulness. In rural districts parents are often ignorant of the advancement education has made since the days when they went to school, and they are often too ready to criticise anything new. The supervisor must gain their confidence, so that they will yield their ideas to his and allow the teacher in their school to follow his directions without any hindrance from them.

The supervisor can exert a wonderful influence in bringing the fireside to the support of the teacher. To do this he must be able to educate the people concerning their relation to the school, as to sending the children regularly, as to providing necessary material, such as books, etc., as to allowing every teacher to pursue those methods of teaching which his skill and experience suggest as best suited to the wants of the school. At meetings of agricultural clubs, at town rallies, at educational "barbecues," at commencements, at spring festivals, at farmers' institutes, he should embrace every opportunity of saying a word for the schools, in order to arouse the people and interest them in the whole system of education. The columns of the country paper afford the supervisor a very ready means of reaching the people. Almost every farmer takes the county paper, which, coming weekly to his fireside, gives the news of the outside world and the doings of his neighbors. School news is an important item and should never be omitted. Every week the paper should contain something of educational interest from the pen of the supervisor, though not always over his signature—suggestions for improvement, statistics of enrollment and attendance, new and better ways of teaching, plans for schoolhouse construction and decoration. The press is valuable to every teacher and helpful to the system of education by bringing farmers into sympathy with the great educational movements of the world. The press gives a larger audience, though it enforces a shorter address. But a little every week, full of variety and interest, will eventually build up a healthy sentiment in the county and educate parents as well as children.

The supervisor should have a direct or indirect control of the selection of teachers. The crisis in the history of schools is when teachers are to be chosen. No one is so well qualified to choose them wisely as a faithful supervisor, and no one is more likely to do so conscientiously, since he knows the value of efficient teach-

ers. This control can be given him directly or indirectly. If he does not wish to have the direct choice in individual instances, the same may be accomplished by giving him the power to examine and license teachers for his supervisory district. No one, then, can be selected by the board of directors except such as are approved by him. He prepares an eligible list to which the board is limited in making its choice. If the superintendent is conscientious and courageous in the preparation of this list, he can safely leave the responsibility of the individual appointments to the board.

In many cases the questions for such examination are prepared at the State office. In some instances the county board conducts the examinations, and in a few the answer papers are sent to the State office for final examination and approval or rejection.

The supervisor should be slow to condemn a teacher who is honestly striving to succeed, but if, after faithful and earnest effort, teachers clearly prove that school-teaching is not their vocation, or, after repeated warnings, teachers will not try to do the right kind of work, it is clearly the duty of the supervisor to report the facts to the directors, and his report should be given great weight by them. The power to revoke the certificate is usually in the hands of the supervisory officer. It should be exercised with great caution and deliberation, but fearlessly whenever there is sufficient reason for it.

Since the supervisor is responsible for school methods and for results in teaching, the arrangement of the course of study and the selecting of the text-books should be largely, if not entirely, left to his direction. It is his particular business to know books as well as to know teachers. It is not to be expected that the men who constitute the ordinary "committee on text-books" and whose daily business has no relation whatever to school texts and their use, can decide what book is best for use in the schoolroom. It is very well to have a committee on text-books composed of the members of the board, to prevent possible abuse, but the advice of the supervisor should have much influence in determining the character of the books used in the schools.

SCHOOL DIRECTORS.

It is important that the relations between the supervisor and the school officers should be clearly defined. The directors[1] stand much nearer the people and have an immediate interest in the welfare of the schools. They contract with the teachers, care for the financial affairs of the district, purchase supplies, and are charged with the general business management.

The success of the school depends very largely upon the kind of men who are elected to that office. In the rural districts especially the duties of the director are mainly of a supervisory nature. He should inspect frequently the schoolhouse and school premises; he should see to it that everything is provided which is necessary for the comfort and convenience of both teacher and pupils, that the outbuildings are in a decent condition, and that the supplies are used with due regard to a wise economy. In the discipline of the school he should give a strong moral support to the teacher, and his influence should at all times be on the side of order and obedience. The board of directors should make such rules and regulations for all the schools under its control as it deems necessary for the preservation of school property, for securing punctuality and regularity, and for the general welfare of all concerned, and it should support the teachers in their rigid enforcement. It should be in constant correspondence with the supervisor, so as to keep him informed respecting the progress of the school, and in case a teacher is derelict in his duties, or if for any reason the school needs a special visitation, it should

[1] Director includes whatever term is used to designate the local school officers in any State, as director, commissioner, school committee, trustee, etc.

inform him at once. On the other hand, it should be the aim of the supervisor to establish the most cordial and intimate relations with the local directors. The supervisor should magnify the office of the director. Whenever he visits the school, he should, if possible, induce the director to go with him. If at such visits they inspect the condition of the outbuildings and the premises, the supervisor can often propose plans for the improvement of the buildings which the director will more readily appreciate and approve.

The inspection of a school by a competent supervisor is an object lesson of importance to the director. He is able to see at what points the supervisor is aiming, and he learns something of his ideas and plans. He will thus be better able to counsel and advise the teacher in the frequent visits which he makes to the school and make more intelligent and specific reports to the supervisor. The practice on the part of the supervisor of calling the directors together at stated times for mutual conference is very commendable. These officers are often ignorant of their duties, but in a large majority of cases they are willing and anxious to learn. There is no more effective way of improving the rural schools than that of instructing and informing the men who have them in their immediate charge. No doubt large sums are lost to the various funds through carelessness on the part of treasurers and secretaries in the rural districts in keeping their accounts. The supervisor should make it his duty to audit these books at least once each year, with a view to accuracy of statistics and economy in expenditures, and this should be one of his duties under the law.

THE VISITATION OF SCHOOLS.

The supervisor's method of visiting schools may be considered briefly. First, he visits schools to see how and what the teachers teach, whether their manner is composed, their method clear and concise, their style interesting; whether they are teaching valuable facts or wasting time on trifles; whether they are teaching what is right or what is wrong. Second, he goes to find out what the pupils know. This is a test of the past work of teachers, which is shown by the general manner of recitation, the promptness with which pupils reply, the amount of information they have, the degree of skill they manifest, or the power of original thinking they have developed. Third, he inspects the physical conditions of the school building and grounds. He should note the condition of the outbuilding, and if he finds them unsuitable in any respect, he should say so frankly to teachers and directors, and insist upon a change at once. The supervisor must know whether good light, good seats, proper temperature and ventilation, and thorough drainage are secured. The supervisor should carefully observe the moral atmosphere which surrounds the school, whether it is on the side of order and obedience, of modesty, and of all those virtues which make the character of the typical American citizen. All these are demanded in order that good teaching may be made possible, and good health and public morals may be preserved.

Such being the purpose of the visit, the supervisor should put himself in easy and cordial relations with the teacher and the pupils, that he may have a true understanding of what each can do. The teacher may conduct one or more recitations in the various subjects of study, in order that the supervisor may see the usual methods of instruction. The supervisor can then suggest improvements if needed, and can even take the class in hand and demonstrate them. That he should ask for a class in any particular study and give the pupils a rigid oral or even written review, while the teacher may be attending to some other duty, is proper, for by this means he can find out how much instruction has been given since his last visit and how thoroughly the course of study is being adhered to. It is, however, often best to allow the teacher to pursue the usual routine of exercises, in order that the supervisor may see the school at its everyday work.

An inspection of the teacher's register should not be forgotten. Such a register

in every rural school should show the name and age of each pupil, the studies pursued, where each class commenced and its progress during the term, so that a new teacher can at a glance understand at what point the study of each branch to be taught is to be taken up. The supervisor should insist that such a register be carefully kept by every teacher under his control.

A private record of his own, in which names, dates, classes heard, condition of rooms and premises, material needed, and general observations are kept, will aid the supervisor. He can by this means trace the development of any one school and can more readily observe whether it progresses or retrogrades.

SCHOOLHOUSES AND FURNITURE.

Before closing, your subcommittee desires to emphasize the proposition that the supervisor should have a controlling voice in the erection of the rural schoolhouse, as respects all its sanitary conditions. Before the contract for a new building can be legally let, the written approval of the supervisor should be necessary, certifying that as concerns heating, lighting, ventilation, and everything which conduces to the health and physical growth of the pupils, the requirements of hygienic rules and sanitary science have been carefully and fully complied with. The rural schoolhouse should be built in accordance with the laws of sanitation and modern civilization (Appendix M). It never will be until the State, speaking through the supervisor, compels it as a prerequisite for receiving a share of the public funds.

The supervisor should not be blind to the small things which minister to the comfort of the pupils. Often the rural-school teacher has received no instruction upon these points. If the supervisor finds pupils facing a strong light, he should call attention to the evils likely to ensue, and suggest a remedy. The same is true as regards unsuitable desks or seats. The necessity of proper ventilation and proper temperature should be constantly dwelt upon. Without a thermometer, with no means of ventilation except the door and windows, the rural-school teacher needs and appreciates all the suggestions an intelligent supervisor may make.

Akin to this is the suggestion that the supervisor should insist that the schoolroom be kept clean and neat for sanitary reasons. The floors should be scoured as often as they are soiled; the wood, trash, and ashes should be carefully kept away from around the stove. The walls should be swept free of dust, the chalk racks kept clean, and the window panes polished. Pupils also should be required to keep their desks in order and their books clean. It is stimulating to the little ones and helpful to teachers for the supervisor to have them show their books and to take occasion to comment on the care or on the untidiness with which they are kept.

No better educational influence can surround the children than a well-arranged schoolroom whose floors and windows are clean, whose walls are free from dust and decorated with pictures, whose school grounds are well ordered and shaded by trees and adorned with flowers, and the school presided over by a qualified teacher who is the personification of neatness and good cheer. Under such conditions the child is self-restrained and respects himself because his surroundings are respectable.

The child naturally puts himself in harmony with his environment. If the teacher is neat and the schoolhouse is in proper order, the pupil will copy the example. Day by day beautiful, comfortable, and clean surroundings will have their ethical influence upon his development, until he comes in time to abhor anything that is not beautiful, well ordered, and clean. This point is too often overlooked in plans for supervision. The reverse of this feature is also true. The rural schoolhouse, generally speaking, in its character and surroundings is depressing and degrading. There is nothing about it calculated to cultivate a taste for

the beautiful in art or nature. If, under the influence of intelligent supervision, this can be changed, it will be a work over which coming generations will rejoice.

"There is scarcely a sounder principle in pedagogy than that care begets care; order, order; cleanliness, cleanliness; and beauty, beauty. Things conspicuously good command the respect of children, invite their imitation, and in ways real, though obscure, sink into their souls and mold their being. The power of good example in men and women no one disputes, but there is power akin to it in things, provided they embody the better thoughts of men and women—a power of which more should be made in school management than is made at present." (Massachusetts State Report, 1895.)

If children are daily surrounded by those influences that elevate them, that make them clean and well ordered, that make them love flowers, and pictures, and proper decorations, they at last reach that degree of culture where nothing else will please them. When they grow up and have homes of their own, they must have them clean, neat, bright with pictures, and fringed with shade trees and flowers, for they have been brought up to be happy in no other environment. The true test of our civilization and culture is the kind of home we are content to live in, and the influences of our schools should help to form a disposition for those things that make home life happy and healthy. If the farmer's boy can be taught to love books when he is at school, he will have a library in his home when he becomes a man; if the farmer's girl can be taught decoration at school, she will want pictures and flowers and embroidery when she becomes a woman.

We appeal also for the influence of classical art in our schools. If we have pictures, why not have reprints of those that have moved the hearts of men? Why not have the best looking down from our school walls? They are within the reach of any purse. One reprint from the great masters is an uplifting influence for all time. Cheap and gaudy advertisements, glaring and painful chromos, depress the true spirit of art and perpetuate the crudeness we seek to overcome.

The same can be said of music. If we are to sing songs, why not sing the songs of masters? They have sung many for children, beautiful far beyond the rude compositions that fret our ears everywhere. Also with literature. Why not read the simple classics written for the little ones, and the greater classics for the older ones? Why not in all things get the noblest and best that the world has given, and use them to help our children onward and upward?

The silent influence of clean surroundings, of cheerful teachings, of classical pictures and music and literature, the presence of flowers and their care, the planting of shade trees and studies of their growth, will be a supervision so constant and so searching that no child can escape it. Under its potent warmth, like the steady, quiet shining of the sun, the child plant grows into all the marvelous possibility of flower and fruit.

SUMMARY.

1. As to the character of the supervisor who is brought in contact with the rural-school teacher in the discharge of his official duties:

(1) He should be selected with special regard to his peculiar fitness for that office. Whether his office is elective or appointive, his qualifications, in order that he may be eligible, should be such as to enable him to challenge the respect of those whose work he is required to supervise.

(2) In regard to his scholarship, it should breathe that essential spirit of learning necessary to making good, strong schools. The position of supervisor should be made professional with a view of meeting the demand for the best education which the rural school can possibly afford. This requires a scholarship which is above that of the ordinary man. The tendency to put persons in the supervisory position who have no mental attainments worthy of mention is earnestly deprecated.

(3) In regard to moral character, the supervisor should be a living, inspiring example of such a life as alone is worthy the Christian civilization of our times.

He should carry with him a spirit of sincerity in his work, so that people, teachers, and pupils may look to him with hearty respect, and with entire confidence in the integrity of his purposes.

(4) In regard to his professional spirit, he should be in touch with the best educational thought of the times, carrying with him to the country-school teacher and to the people of a rural community the freshness and life which come from reading and studying whatever bears upon the questions he is called upon to aid in solving. He should be a leader, endowed by nature with strong native sense, and at the same time able to impart enthusiasm and energy to all with whom he comes in contact.

2. As to the purposes of rural school supervision:

(1) It should serve to inspire and stimulate the rural-school teacher. If the supervisor is alive to his opportunities, every teacher within the sphere of his influence will be quickened and lifted up to higher efforts for the good of the school. The teachers should learn to look upon him as a friend, and not as a critic; as a wise counselor, and not as a mere fault-finder.

(2) It should be the means of awakening and stimulating the pupils as well as the teacher. They should look for the visits of the supervisor with pleasure, and profit by his talks and advice. By instituting a system of central examinations for the rural schools, he may quicken and encourage the brighter pupils to obtain the best education within their means. The influence of a scholarly supervisor over the pupils is a very desirable thing in the rural school.

(3) The improved condition of the rural schoolhouse is a sure index of the work of a competent supervisor. The present lamentable condition of these buildings is due largely to ignorance and neglect. Competent supervision in skillful hands can work a marvelous change. The cultivation of a spirit of order and neatness, which leads to the ornamentation of the school grounds and to a watchful care over all the environments of the schoolhouse, is one of the purposes of supervision.

(4) Supervision does not accomplish its legitimate purpose when it fails to cultivate a strong, healthy public opinion in favor of everything which tends to make a good school. Hence the supervisor who contents himself with a perfunctory visit to the school only is not a supervisor in the broad sense of that word. A large share of the work of the supervisor is away from the school and among the people.

3. As to the results to be expected from intelligent supervision:

(1) In regard to the school, it unites teachers for a common purpose, and, by teachers' meetings and by the visitations of the supervisor, it breaks up the monotony and isolation of the country school. Under its influence better teachers find their way into the schools, better methods of instruction prevail, and the tone and spirit of the school are greatly improved.

(2) In regard to the community at large, supervision is just beginning to do its legitimate work. In the establishment of school libraries, in the relation of the supervisor to the directors, in an improved school architecture in which due regard is had to sanitary conditions, in the ornamentation and care of the school grounds, in school extension, in the introduction of studies which will add to the attractiveness and profit of life on the farm, in the consolidation of small districts into larger and stronger schools, in awakening a public interest in rural education, there is a field large enough to occupy the time and thought of the most progressive and most intelligent supervisor. It is here we are to look in the near future for the best results of supervision as concerns the rural schools of the country.

LAWTON B. EVANS, *Chairman.*
CHARLES R. SKINNER.
HENRY SABIN.

REPORT OF THE SUBCOMMITTEE ON SUPPLY OF TEACHERS.

The subcommittee on supply of teachers has distributed a large number of circular letters of inquiry, designed to elicit information in regard to the agencies now existing for the preparation of teachers for rural schools, and for the improvement of teachers already in the service, and also in regard to certain conditions, as to the manner of certificating, employing, and paying teachers, which affect the supply. In connection with this inquiry the attempt has been made to gather information as to the defects and excellencies of existing systems, together with suggestions for improvement. To these a sufficient number of replies has been received to justify the belief that they give a fair average statement of the conditions which this report has to meet. Without attempting to summarize the returns, your committee would state the results of the inquiry upon the problem presented and mark out the lines which must be followed, and to what end, in order that the child in the country school may receive the education which is his due. In some State systems progress along these lines is much more advanced than in others, and in some individual cases the desired end has been attained; but this is true, as regards the entire country, in so small a degree that it is unnecessary, even if it were possible, to particularize. With but few exceptions the recommendations made could be justified by reference to various States or communities in our own country, and there are none which do not rest upon successful experiences at home or abroad. It will be found quite impossible to treat the rural school in any of its aspects without touching in some degree upon ground common to all classes of schools, and this is especially true as regards that branch of the problem assigned to this subcommittee.

Certain conditions now very general must be changed in order that the rural school may be supplied with better teachers.

TEACHERS.

There must be in rural communities a clearer appreciation of the qualities essential to a good teacher. It is too often the case that no distinction is made between a teacher of superior scholarship, of proved ability in instruction and discipline, of long experience, and one far inferior in all the qualities essential to success.

The teacher must be engaged for the school year. In many cases the engagement is from term to term, and these frequent changes are, without exception, classed among the most potent causes of failure in the rural school. It is widely true that the school is in session less than half the year; it is often true that in this short school year two teachers are employed, and seldom does a teacher remain a second year. Engagements should be for a longer term than one year, or continuous, and terminated only for cause, as is the case in many cities.

One of the most important points to be considered in a system of schools is that of the authorities employing teachers and assigning them to their work. In cases in which the county or township is the unit of school administration, the problem is solved; in case the district system prevails, the district containing one school, it is evident that the employment and assignment of teachers should be transferred to the authorities of the larger school unit, in order that in the assignment advantage may be taken of peculiar abilities and aptitudes.

The authority which examines should not employ.

Closely allied to this question is one of great interest in the Southern States, namely, that of assignment of teachers to negro schools. For a full treatment of this subject see Appendix J.

SCHOOL YEAR.

The school year must be lengthened to a full school year of nine or ten months. In many States a minimum length is prescribed by statute, but in few cases is this

sufficient. Whatever efforts may be made for the improvement of the rural school, until there can be offered a "year's work and a year's wage" it will be difficult and often impossible to retain accomplished teachers for continuous service; with this, many such teachers would choose this service from family and social connections and from a natural preference for rural life.

In countries in which people are accustomed to the action of centralized authority prescription settles the matter, as in France, where the school year is more than forty weeks; in England, where, as conditions of receiving the Government grant, the principal teacher at least must hold the Government certificate of qualification, the school premises must be in good sanitary condition, the staff, furniture, and apparatus must be sufficient, and the school must have met four hundred times (two hundred days) in the year.

In countries like our own, in which popular initiative in political matters has been the rule, success must usually come by other methods, and in this respect we have much to learn from our neighbors. In Canada the schools have been lengthened to a full school year mainly under the stimulus given by the mode of distributing the Government grants.

Letters and reports have been received from the different provinces. By these it appears that the average length of the school year was in Ontario 212 days; in New Brunswick, 216 days; in Nova Scotia, 198.7 days, the full school year being 216 days and some schools exceeding this limit. A report from Regina, the capital of the Northwest Territories, states that the full school year is considered to be twelve months, less the holidays, amounting to seven weeks, but this limit can not be attained where the sparseness of the population obliges the pupils to travel long distances, on account of the severity of the winters.[1]

Adding to our plan of requiring a minimum school year the Canadian plan, already in a degree recognized in some recent school legislation, of making the amount of Government grant depend, in a large degree, upon the length of the school year and the average attendance, consolidating schools wherever practicable, and giving from the larger units of school administration to aid the smaller and weaker, the obstacle of the short term and insufficient compensation can be removed.

SUPERVISION.

Incompetent supervision forms one obstacle to a supply of better teachers. This obstacle may be removed by securing professional supervision, as is provided by the plan of district supervision so successfully applied in Massachusetts and just enacted in Maine. The subcommittee on supervision treats this subject fully.

It is necessary that more definite tests of professional fitness for the work of supervision be instituted. The extension of pedagogical instruction in colleges and universities in recent years is gradually elevating the work of supervision to a higher pedagogical plane, yet the point has not been reached of demanding professional preparation as an essential condition. For examples of the requirements of more definite tests of fitness see Ontario and France (Appendix N).

It is not unreasonable to hope that in the not distant future the popular standard of education may be so raised that on all educational boards of control, from the State board down to the county or township school board, so much of pedagogical fitness, from the professional point of view, may be demanded as to insure the intelligent consideration of such questions pertaining to the profession as may come before them.

There are various recognized agencies for the improvement of teachers.

---

[1] The subcommittee is under obligation to more than it can name, throughout the United States, for information. For aid in its inquiries received from the provincial school authorities of Nova Scotia, New Brunswick, Quebec, Ontario, and Manitoba, and from Mrs. Etta F. Grover, of Regina, Assiniboia, and Mr. Chisholm, principal of the high school in Regina, it would here express its thanks.

ASSOCIATIONS.

The State associations are mainly in the control of teachers representing systems of schools; in but few States are rural school teachers much in evidence at these meetings. The fact that in some States the opposite condition holds shows that the State association may be made a powerful means of uplifting for the rural schools.

In many of the States vigorous county associations are found, although this is by no means universal. In these the rural school receives more recognition, but not often all which is its due. When the county association holds frequent sessions and makes the interests of the rural schools prominent, it proves one of the most efficient agencies.

Some of the States report local associations of rural school teachers which are very efficient. Generally the success of these is largely dependent upon the spirit of the local or county superintendent. With good professional supervision in township and county, the wants of rural schools and their teachers can find due consideration in local and county associations; and by proper organization of rural school sections in the State associations there may be secured such an affiliation of State, county, and local associations as will insure in time a full recognition of the peculiar needs of the rural schools.

It is desirable that the affiliation between these associations be such as to secure in part the working together, along the same lines of thought, during the same years, by the local, county, and State associations, under the inspiration of the State department of education.

SUMMER SCHOOLS OF SEVERAL WEEKS' DURATION.

In some cases summer schools are apparently conducted for the purpose of enabling those attending to pass examinations for certain certificates. The tendency is necessarily toward cramming for the examinations, and so far they cease to be educative in any proper sense of that term.

There is another class of summer schools, often held in connection with colleges and universities, conducted by able teachers, specialists in their departments, for the purpose of advancing education along true lines. Among these, the Agassiz School at Penekese, many years ago, was a revelation and an inspiration to the teachers of the United States. These schools have multiplied in number and enlarged in scope throughout the land, and have proved of great advantage to thousands, not only by increasing their knowledge, but also and much more by bringing them under the personal influence of leaders of thought and masters in teaching.

A third class, with professional courses in psychology, pedagogy, and methods, often combining the character of the second class, preceding, offers great advantages for professional improvement. There should be in every county one of these for the especial benefit of teachers of the common schools; they should be free of tuition, organized and conducted under the supervision of the State department of education, continuing from four to ten weeks. There should be provision for practice teaching, and the instructors should be familiar with rural schools, their condition and needs.

INSTITUTES.

The normal institutes, so called, organized in some States, especially in the West, are essentially the same as the third class of summer schools described above.

County institutes of one week or more, held during the school year, may exert a great influence in the improvement of teachers. When they are conducted under efficient supervision, with a body of instructors capable of increasing the range of thought of teachers, and are organized under such laws as will secure the attend-

ance of the teachers of the county, they prove a powerful means of educational advance.

For the description of such an organization of institutes and results see Appendix P.

Teachers' conventions or institutes of one day, as conferences between teachers, or with superintendents, will prove effective to a greater or less degree according to the purpose, plan, and mode of conducting. In order to secure the best results, they should be held at intervals so frequent that the effect may be continuous.

READING CIRCLES.

The success of the Chautauqua movement, of various organizations for home study, and of teachers' reading circles, in some cases, proves that these may be made generally efficient. There will be no lack of interest on the part of the teachers, if the organization and direction be wise.

The problem is apparently not a difficult one in the larger places, with systems of schools, where numbers of members are readily brought together, but the case is quite different in the case of rural schools. The results reported clearly indicate certain elements essential to success. To secure the advantage of organization there must be a central board of control. This may be a State board with auxiliary boards in counties and towns. Not only are books for reading to be selected, but a plan of work should be carefully drawn up and widely circulated among teachers. The central board should keep in touch with the members of the circles, papers based upon the books read should be written and carefully examined, and the results attained should in some way be passed to the teacher's credit; thus, for a certain number of certificates indicating the completion of a course, a diploma may be granted.

The plan of organization is perhaps best formed by the teachers of the State acting through their associations, and the courses of reading can best be made out by the committees chosen by the teachers for this purpose. The work may be directed by a committee, but, from comparison of results reported, the varying degrees of success, and the many failures, your committee believes it desirable that there should be in the State department of education a bureau of teachers' reading circles, with sufficient force to keep in touch with the local circles, to conduct and encourage correspondence with them, and in every way to promote their interest and efficiency.

Effective study demands the use of books for consultation and reference. Hence the reading circles should be conducted in conjunction with the lending libraries hereafter mentioned.

The reading circles must be considered as a means of improvement, especially for teachers already in the service. No other agency can really take the place of personal instruction in the original preparation of a teacher for his work.

LIBRARIES.

The country town has suffered, and still suffers, from the lack of books. In many States there is now a movement toward the extension of free-library privileges, and wherever there is a town library every school should be made a branch. This system of library extension, becoming universal in cities, can be extended to country as well. By frequent exchange of books, under the immediate direction of the teacher as branch librarian, every teacher and pupil will have the use of a larger library in addition to the special library which should be found in every school. Some books should be added to the library for the special benefit of teachers.

The library belonging to the school is a necessity. Books lent for a time serve their purpose, but a love for good books and the ability to use them aright come most surely from daily companionship. From the library center the school can

be carried into the home. A more valuable work can hardly be done by the rural-school teacher than this, of developing a love for good reading.

In addition to these, there should be established in the county, or the State, or both, a professional library for the use of teachers. This might well be a State library with county branches, and the management of it might well be under the bureau of reading circles which has been mentioned. Such a State school library has been established in New York (Appendix L).

TEACHERS' TRAINING CLASSES.

The agencies thus far treated tend to the improvement of teachers already in the service; none of them furnish a first supply for rural schools, and there is a lack of special agencies designed for that end. The investigations of your sub-committee show that the existing normal schools in general do comparatively little in this direction, except by the teaching of their undergraduates. Although originally established for the benefit of the common school, they have naturally tended to keep step with the development of systems of schools in cities and large villages. The majority of rural teachers, often a vast majority, are now without any professional preparation whatever. The tendency is strikingly shown in returns from the Oswego (N. Y.) Normal School: "Nine-tenths of our pupils come from the country. Not one-tenth ever teach in rural schools." In one of the older States, after many years' existence of normal schools, of more than 12,000 teachers in the public schools of all classes less than 5,000 have ever attended normal schools, less than 4,000 have graduated from normal schools. Over 1,500 vacancies occur annually in the schools of the State. The normal schools of the State graduate about 300 annually, nearly all of whom become teachers in graded schools.

One of the leading States of the Union, with a well-organized school system and a grand equipment of normal schools aiming directly to train teachers for the rural schools, reports that a majority of its teachers have not had professional training. Many other States report a much smaller proportion of trained teachers—one, 8 per cent; another, with one of the best school systems, 30 per cent. As a contrast, an answer to the inquiry of your committee, from Manitoba, states: "Sixty-six per cent of the teachers employed in the Province in 1895 were trained. After this year all will have training." (See Appendix N.)

The cause for such a contrast appears later in this report.

The normal-school system was first devised especially for the benefit of the rural schools, and in obedience to a tendency which had become increasingly strong for some years previous to the time of their establishment. Some brief passages of educational history bearing upon this subject are here cited:

In 1823 Samuel Reed Hall opened a normal school in Concord, Vt., a school for the academic and professional education of common-school teachers, with a school for practice in teaching. Here Mr. Hall's lectures on school keeping were delivered to his class. These were afterwards published. The character of his work led to his being called to the principalship of the English department of Phillips Academy at Andover, Mass. He was afterwards invited to take charge of Holmes's Academy, Plymouth, N. H., and consented on condition that the school should be called a teachers' seminary. He opened this teachers' seminary in 1837 and continued it two years. In this school there was a classical department and no practice school, but the course, as printed in Appendix K, shows the pedagogical character of the institution and the provision made for its students to gain experience in teaching.

In 1829 a training school for teachers of the common schools was opened in the town of Effingham, N. H., by Hon. J. W. Bradbury, ex-United States Senator from Maine, now living, at more than 90 years of age, in Augusta, Me. By

request, Hon. W. W. Stetson, State superintendent of Maine, recently visited him to ascertain the facts in regard to this school, and the interview is annexed to this report as Appendix K.

The sole purpose of Horace Mann in the establishment of the first State normal school in Massachusetts, a purpose zealously carried out by the principal, Cyrus Peirce, was to elevate the common schools of the country. The course of study of the normal school was for one year. In the first year of the school a model school was organized, in which normal-school students had daily practice in teaching. Mr. Peirce himself taught in the model school, as he felt that upon its success the success of the normal school very largely depended. Almost all the pupils at first came from country towns; almost all returned to teach in country schools. There was not then the difference between the rural school and the city school which now exists. In 1847 John D. Philbrick began the experiment of modern grading in Boston, and, with the full development of this system, later, the contrast between the school of the country and the school of the town became more and more marked, and the rural-school problem appeared. The normal-school course, at first simple and adapted to the conditions it was designed to meet, developed to keep pace with the developing school system, and gradually drew away from the rural schools.

The normal school is often removed still further from those who would teach in rural schools by the tendency to raise the standard of admission to the requirements of a high-school course. The fact that most of the towns of the State have a high school is no proof that all those who will teach rural schools can go through a high-school course of three or four years, and then a normal-school course of two or three years. Great care should be taken that the normal school does not get too far from those whom it was especially set to serve. There is needed a more careful determination of the qualities and attainments requisite for entrance upon the work of preparation for teaching. These are sometimes given in larger measures by the experiences and responsibilities of country life than by the graded city high school, and with these every added step in education is great gain. So far as raising the standard of admission is in response to a claim that all academic studies should be taken out of the normal-school course, it may be said that the claim is not universally recognized as valid by those who have had most experience of work at home, and can find but little warrant abroad. In the normal schools of Prussia, Austria, Switzerland, and France, for example, a larger proportion of time is given to academic studies than in many of the normal schools of the United States,[1], but with directions, certainly in France, that in all the course the professional aim shall be constantly kept in view.

It is evident that for the fitting preparation of teachers for the rural school some agency is needed intermediate between the brief convention or institute and the normal school, with its two or four years' course, so far beyond the reach of the majority of rural-school teachers. What shall it be?

Several facts must be kept in mind in the solution of the problem: (1) A large proportion of the teachers of rural schools can not afford the time and expense of a two-years' course in a normal school. (2) The receipts from employment in the rural school under present conditions do not remunerate one for the expense of a normal-school course. This is a simple matter of business, and sentiment will not change the facts. (3) Other conditions remaining the same, attendance at a school is in an inverse ratio to the distance between school and home. This is especially true for a short course.

To meet these conditions there is needed a normal training school with a short course of study. The place is a village which will give over its schools to this

[1] See Report of Committee on Normal Education, Proceedings of National Council of Education, 1892.

normal training school for practice schools. These practice schools, organized as primary schools in one room and as grammar schools in another, will show what can be done with schools in the simplest form of gradation. For a part of the course all the grades should be brought together to illustrate the work of the one-teacher school, such work as should be done in the ungraded school. A faculty of five or six good teachers, including practice-school teachers, would suffice for such a school.

This the general organization—what the work? Treatment of matter essential to good teaching would be grounded on simple fundamental principles. Deficiencies in education would be supplemented by sound teaching; principles of teaching and of school management would be taught and illustrated. Many might learn to do well what they had never done at all; most would learn to do better what they had done poorly. From these schools would come many students for fuller courses of training and a still wider usefulness.

This plan in its development would give a system of district training schools analogous to the county model schools of Ontario and the training schools of Quebec and Manitoba, with a course of study and training of one year, the first half of which should be mainly academic, for those who need this preparation, the second half mainly professional, the work so planned that those of more advanced scholarship need take only the course of the second half year. Of these schools there should be at least one in every county of the State (Appendix N).

The practice in teaching should be thoroughly organized. Every teacher in the school should be, in a certain sense, a training teacher. He should be responsible for the methods of teaching in his own subjects, and should direct lessons given by members of his classes to children from the model training schools. Besides such lessons illustrative of methods of teaching, the pupil teacher should be trained in conducting school work in the schoolrooms under conditions similar to those which she will find in her own school. While teaching in the practice school under the direction of a teacher in charge, she should be left more and more to her own judgment. She should be held responsible for the control and direction of the school, and for the teaching of a class, not merely of a group.

The membership of the class for training should be limited to such numbers as will give the full advantage of the training course, or, with a practice school of the size presupposed, to about twenty-five. A large class necessitates the teaching of groups, not of full classes with the control of a school. The French law limits the number of students in each normal school to three classes of twenty-five each.

The practice schools should be under the exclusive instruction and control of their regular teachers a sufficient proportion of the time to keep them up to the standard of veritable model schools as well.

The completion of this course should give a teacher's certificate of elementary grade, which would also give admission to the State normal school, with due credit on the normal-school course for work already accomplished.

There should be a summer term for rural-school teachers in every normal school in the United States. The plant of the normal school has cost thousands, in some cases hundreds of thousands, of dollars, and for two or three months in the summer this investment remains entirely unproductive. The success of the summer term in the University of Chicago is significant, and the Winona plan, adopted this year in all the State normal schools of Minnesota, sets the example for the nation (Appendix S). In normal schools the work of the first year, or the first part of the course, should be so planned as to have a unity in itself as a preparation for rural-school teachers, and the results accomplished in the summer term should count on this course, so as to encourage subsequent attendance at the normal school. The summer term should not be an institute, nor a summer school, in the usual sense, but should combine the elements of the other terms of

the year. The attendance of children in the training school could be secured easily for two or three hours a day.

There should be organized in all States a system of normal-school extension analogous to the university extension. Wherever a class of sufficient size can be formed, a teacher should be provided. The work should be so organized and conducted as to lead to definite results which can be credited to the members of the class.

There are two possible agencies in the preparation of teachers for rural schools that have not been mentioned:

1. *City training schools.*—In large cities it is not to be expected that the city training school will prepare teachers for rural schools; all their graduates usually find employment at home. But cities in this country with a population of more than 50,000 are comparatively very few, and it is reasonable to suppose that training schools in cities of less than 50,000 will prepare more teachers than can be provided with employment in those cities. The surplus will naturally seek positions in the village and country schools.

Birmingham, Ala., a city of about 50,000, has had a training school for eight years. During that time 25 per cent of the graduates of this school have found employment in the ungraded schools of the county and State. If the training school is encouraged, it can be made an important factor in the preparation of teachers for rural schools. A part of the course in these schools should, therefore, deal with the conditions of the ungraded schools of the county, and the instruction should be specifically adapted to meet those conditions.

2. *Agricultural colleges.*—Many pupils in agricultural schools and colleges teach during their course. In some cases the agricultural college is brought nearer the people by the establishment of branches. Thus in Alabama there has been established in each Congressional district a branch agricultural school, closely related to the agricultural and mechanical college of the State. Can not such schools accomplish much in the specific preparation of teachers for the work of the rural schools?

3. *High schools.*—An effective auxiliary in the training of elementary teachers may be found in high schools. In 1894–95 there were in New York 247 such classes, with 2,482 students. The regulations prescribe the professional qualifications of the teachers who are to instruct these classes, and the equipment and the opportunities for observation and practice to be furnished. The course of study, extending through one year, covers the ground of common-school studies, including with subject-matter the treatment of methods of teaching, the history of education, school management, and school law. The school is to furnish each day the opportunity for the class, or some members of it, to observe methods of teaching in the several grades of common-school work, and, when practicable, the opportunity to teach in such grades under proper criticism and direction.

A system similar to this is in operation in the Province of Quebec.

Although these training classes can not take the place nor do the work of special training schools, yet they offer a ready means for effecting some immediate improvement in the teaching force of the State, and for the selection of those who have such fitness for teaching as will justify their pursuing a special professional course. The teachers of such classes must themselves have received thorough pedagogical instruction, else the result must be a failure; hence the necessity is apparent for pedagogical courses in all colleges.

According to the generalizations of the Superintendent of the last census, over an area of our country of 1,688,827 square miles, containing a population of 2 to 45 to the square mile, the occupation of the people is mainly agriculture; of this territory 1,096,790 square miles are occupied by a people mainly engaged in systematic agriculture, leaving about 260,000 square miles, with a population of 45 and upward to the square mile, in which the leading interests are commerce and manufactures, and in which professional and personal service are in large

demand. The numbers engaged in the principal occupations in the United States, according to the latest United States census, were as follows:

Farm and garden	8,375,979
All the professions	944,323
Domestic and personal service	4,300,506
Trade and transportation	3,325,962
Manufacturing and mechanical industries	5,091,669

In behalf of all these occupations, except the professions and agriculture, the claim has been made and has been allowed that special instruction in their interests be made an important part of the school curriculum—in commercial courses; in cooking; in manual training, on which such vast sums have been expended. Indeed, for many of the professions much of the school instruction is a direct preparation.

Much is said of the necessity for considering the environment of the child; for bringing into his school life the thoughts and interests of his home life, that the school may not prove to him a thing remote and foreign; of making the school a recognition of his past and a preparation for his future. Little sign of this can be found in the ordinary rural school.

The courses of study in the normal school of all grades should recognize more fully than they do the environment and probable future life of the children in the schools, or rather, they should recognize the lines along which lives of most probable future happiness would lie. As has been shown, much the largest class of the workers of this country is engaged in agriculture. The environments of their children are rural. The rural school should aim especially to make country life more attractive and beautiful, and should pay more attention to rural industries. Every normal school should have as a means of instruction a school garden, planned and conducted not merely to teach the pure science of botany, but also the simple principles of the applied science of agriculture and gardening; and every rural school should also have its garden, through which the training of the normal school may reach the home. This element of industrial training should be especially emphasized in the colored normal schools and rural schools of the South.

Other countries lead us. A farm has been set apart for this line of instruction at the Provincial Normal School at Truro, Nova Scotia. The school garden is common in the countries of Europe most advanced in popular education. The school garden and the nursery of fruit trees are a feature of the normal schools of France; there is a course of agriculture in the normal schools for men, of horticulture in the normal schools for women.

The course in agriculture treats of preparation of the soil, special culture of trees and shrubs, of fruit trees, grafting, and the vegetable garden.

The course in horticulture in the normal schools for women treats of the garden in its general arrangements—the fruit garden, the vegetable garden, the flower garden.

Each garden has a space reserved as a botanic garden for instruction in the science of botany.

The instruction received in the normal school is applied in the school garden of the rural school.[1]

[1] The school garden in the New Hampshire State Normal and Training School has proved a source of interest and of instruction to pupils of all grades in the training schools and in the normal schools, such as nothing else can replace. In this garden all the grains and vegetables grown in the region were cultivated, together with a great variety of flowers. Each class in school had assigned to it a plot, for which it was responsible. In the George Putnam School, in Boston, a part of the school yard was turned into a garden, which has received several prizes from the Massachusetts Horticultural Society. On certain days the Jardin des Plantes in Paris is used as a place for botanical study by the school children. I found once on the roof of a London schoolhouse, which was used as the girls' play ground, a large and beautiful collection of plants. And yet the rural school almost utterly ignores its only possible laboratory, the out of doors, the garden laboratory, right at hand. Here lies a duty, not a choice merely, for the normal school.

A French report says that the French farmer is at first opposed to book farming; but when he sees that the products of the teacher's garden are superior to his own, he is glad to learn.

M. Boutan, an inspector-general of public instruction, says in a report: "We can cite several departments in which, thanks to the initiative of the teachers, the wealth of the country has increased from year to year, and from which the exportation of fine fruit has become the source of considerable profit."

There can be no doubt that great improvement in agriculture might result from the general diffusion of such instruction through school gardens, under the direction of qualified teachers. Is there any other means for such improvement in sight of this generation? And a still higher good for the country life might come from thus blending its utilities and its beauties in the thought of the child.

Your subcommittees would also emphasize the importance of two other lines of work already developed in the graded schools, and of a third, which must be made prominent in all schools—language, elements of science or nature study, and morals. Whatever goes into the common school must go into the normal school. Hence, even in the brief course of normal-school training, the instruction in the English language, instruction in the essential elements of its beauty and strength, instruction leading toward such command of its best forms as will tend to make it a transparent medium for the expression of thought, must be held of fundamental importance. There must be such training in elementary science and in manipulation as will give the teacher essential knowledge and skill in this line of teaching, and there must be such instruction in elementary psychology and ethics as is necessary for the comprehension of general principles of method, and of the scope and methods of instruction in morals; and as result of all the preparation which can be given there should be a clear comprehension of the essential aims of education. Would that all our teachers could have constantly in mind and at hand such a statement as is found on the desks of the common-school teachers of France (Appendix R).

EXAMINATION AND CERTIFICATION OF TEACHERS.

Were teaching a profession in the sense in which law and medicine are professions, teachers themselves would formulate the terms of professional recognition; but evidently the time for that is not yet. What the public school is immediately to aim for is uniformity in State examinations, and we have to consider the agencies, the standards, the methods for these examinations. The agency may be the State superintendent of public instruction, a special examining board, or a State board of education when such board exists. Times and places for examination should be announced frequent enough and numerous enough to meet all reasonable demand. The scope and character of the examinations should be announced long enough beforehand to enable candidates to consider the matter deliberately, as is now done in regard to examinations for admission to college and for the civil service. Information as to books for use and as to modes of preparation should be given. Each examination should be conducted by an expert, and the papers should be critically examined.

Certificates granted should be graded as to the range of the examination, not as to length of validity, unless the certificate be a provisional one. A one-year physician would receive little credit; why should a one-year teacher receive more?

Examinations should cover the range of work required of the teacher, and should be written, oral, and practical. The written examination should be planned not merely to test the candidate's range of acquirement, but rather his accuracy, his general style of thought and expression. The oral examination should test the range of attainment, the personality of the candidate, and his readiness in resource. These two are generally combined in one—the written form, but there are great advantages in the separation whenever it is practicable.

The examination for the elementary certificate should cover the ground of common-school studies, with so much of the elements of natural science as is demanded for the intelligent teaching of the nature lessons in the common-school course. The questions should be few, but comprehensive, and such as will fairly test the reflective power of the candidate.

The professional examination for the elementary grade of certificate should not be severe, but should require clear general statements regarding methods of conducting recitations and the organization and management of a school.

The practical examination, or the test of skill, for the elementary grade of certificate, should include some test of the candidate's ability to plan a lesson and an examination paper in some common-school subject, and to conduct a recitation. If the candidate has been a member of a class in training, a record of this practical work might be brought over from the work in that class.

So much ability as is implied by this examination is necessary to the good teaching of any school. Wherever this ability can not be secured now for the rural school, a clear public appreciation of the need will lead to a supply of the means.

The examination for the advanced certificate should in general cover the ground of an English high-school course of at least three years, or fair equivalents for such a course. A special certificate might be given for a foreign language. This examination should include psychology and ethics, drawing, and the elements of vocal music.

The professional examination for the advanced certificate should include history of education, methods of teaching, general principles of pedagogy, and the organization and management of schools.

The practical examination should include the preparation of plans of lessons and of examinations; judging the character of a lesson and a written paper; teaching, including an oral lesson on some subject in nature study, elements of science, language, or morals.

As in the examination for the elementary certificate, if the candidate is a member of any training class, the practical examination can be taken in that class.

Formulating the preceding statements, the teachers' certificates should be graded in two general classes, elementary and advanced, and in each class three grades.

ELEMENTARY:

(1) Elementary scholastic certificate, grade 3.
(2) Elementary professional certificate, grade 2.
(3) Elementary certificate of skill, grade 1.

ADVANCED:

(1) Advanced scholastic certificate, grade 3.
(2) Advanced professional certificate, grade 2.
(3) Advanced certificate of skill, grade 1.

A life certificate of either class and honorable recognition in the profession should be granted after a certain period of successful teaching to those holding the first-grade certificate of that class.

In each class the higher certificate presupposes the lower; thus grade 1 can not be obtained without 3 and 2.

Many, if not most, of the examinations of teachers for rural schools in the United States to-day do not go beyond the range of the elementary certificate, grade 3, as here given; the elementary certificate, grade 2, could be obtained by attendance upon a teachers' training class in a high school. A course in a district training school organized as described in this report, or a partial course of one year in a State normal school, should give the complete elementary certificate. In many cases thoughtful and successful teachers in the rural school, by their own study and the help afforded by a well-conducted reading circle and a

normal extension course, could rise from the elementary certificate, grade 3, to the complete elementary certificate. A high-school course would give advanced certificate, grade 3, and, with the course in a high-school teachers' training class, might give advanced certificate, grade 2. The complete advanced certificate could be obtained by a two-years course in a normal school.

This gradation of examinations and certificates will utilize to the utmost the existing educational agencies, will point out to teachers a way in which they may rise step by step, and will thus encourage their advance, and will secure to the rural school the benefit of their improvement.

A question will arise as to the interval between the elementary and the advanced certificate. (For a wider interval established in Manitoba see Appendix N.) In many cases it may be best to lower the standard of the advanced certificate and make it intermediate between the elementary certificate and the normal-school diploma attesting the completion of a two years' course. On this question your subcommittee pronounces no opinion. It would point out a way by which the teachers of the rural school as it now is may be taken as they are and induced to enter upon a course of advanced study, and by which the school may derive all possible benefit from the advance; and your subcommittee believes that by such a course standards will gradually be raised all along the line.

Your subcommittee on the supply of teachers for rural schools, in closing its report, would call attention to some of the main points in this discussion.

It appears that there are numerous agencies which may be made available for the improvement of rural-school teachers already in the service. With these the only question is that of more perfect organization.

Although there is in general an increase in interest in educational questions and an elevation of standards of teaching, yet the large majority of rural-school teachers now enter upon their work with no professional preparation; the improvement in the character of rural schools, where there has been any improvement, has been slow; large sections of the country report no advance; some report a decline.

The causes for this condition and the changes needed are not far to seek:

1. The school year must be lengthened to a full school year of nine or ten months, in order that skilled teachers may be retained. This result can be secured, as it has been secured elsewhere when its absolute necessity has been recognized. The State, among other conditions for payment from the school fund, may prescribe a full school year, which is done in England, as logically as six, or seven, or eight months, now done in some of our States; or it may secure this result, as it has been secured in Canada, by making the length of the school so prominent a condition in the distribution of the school fund as to insure the cooperation of the county and the town to this end.

2. The existing agencies for the supply of teachers for rural schools do not suffice. There must be modifications in these and the provision of others.

3. There must be some definite standard for the certification of teachers, coming within reach of the teacher of the rural school, and encouraging advance to such higher degrees of attainment and skill as will give full professional recognition. And your committee believes that some provision should be made to secure interstate recognition.

The question of finance does not lie within the province of this subcommittee, but it does not believe that the financial difficulty need prevent the necessary reform. When there is once full recognition by the State of its final responsibility for the education of every child within its borders, there will be possible such an adjustment of expenses between it and the lower educational units as will be burdensome to none and just to all.

Your subcommittee has sought to ascertain accurately what the rural school now is; in all its suggestions it has had in view the rural school as it ought to be.

It believes that this nation can have such a system of schools for all its people as may challenge comparison with any other, and that it will have such a system when it clearly perceives the injustice and the peril of the present condition and the way in which safety lies.

CHARLES C. ROUNDS, *Chairman.*
DAVID L. KIEHLE.
JOHN H. PHILLIPS.

REPORT OF THE SUBCOMMITTEE ON INSTRUCTION AND DISCIPLINE.

Your subcommittee on course of study, methods of instruction, and discipline in rural schools begs leave to report herewith that it has carefully considered the conditions which prevail in thinly settled districts with the intent to discover the evils that exist in the schools as a consequence of those conditions, such, for example, as (1) the want of classification and (2) the impossibility of thorough instruction on the part of the teacher, as well as (3) the lack of that stimulus which comes to the pupil from working at reasonable tasks in company with his equals. Your committee has hereinafter described and discussed various remedies, which it believes will have useful results in practice.

About one-half of all the teachers in the United States teach what are called ungraded schools. They receive in one room pupils of all ages and all degrees of advancement from A B C's upward, sometimes even to algebra and Latin. In extreme cases each pupil is a class by himself in all branches, except perhaps reading, writing, and spelling. It quite often happens that there is no uniformity of text-books, each pupil having a different edition or different author; the teacher is often obliged to borrow the pupil's book when he hears him recite.

According to Mr. Hinsdale's studies of the United States census (see Appendix A), the sparsely settled region of the country includes, first, one-third of the whole domain entirely uninhabited or containing fewer than 2 inhabitants per square mile; secondly, an area of 1,688,827 miles with from 2 to 45 inhabitants per square mile, leaving only 260,000 square miles containing more than 45 to the square mile, and the 443 cities with an aggregate of nearly 19,000,000 people.

It happens that ungraded rural schools with a very small attendance are to be found even in the most thickly peopled States and often in proximity to cities. Rhode Island in 1895 reports 158 out of its 263 schools as ungraded and 64 of them as containing fewer than 10 pupils each; 8 towns have in the aggregate 39 schools averaging fewer than 10 pupils. Vermont in 1893 reported 153 schools with 6 pupils or less each. Massachusetts in 1893–94 reported 16 towns with an aggregate of nearly 100 schools with an average of 11 pupils. New York in 1894–95 reported 2,983 schools with fewer than 10 pupils each and 7,529 with less than 20. Other examples are mentioned in the report of the subcommittee on maintenance.

A school with 10 pupils of ages from 5 to 15 years, of different degrees of advancement, some beginning to learn their letters, others advanced from one to eight or nine years in the course of study, can not be graded or classified to advantage, but must for the most part be taught individually. The beginner who does not yet know a letter should not be placed in a class with another who began last year and can now read lessons in the middle of the primer. It will not do to place in the same class a boy beginning numeration and another one who has already mastered the multiplication table. The beginner in grammar has not yet learned the technique, and is confused and discouraged by the instruction given to another pupil in his class who has already learned the declensions and conjugations.

Any attempt, in short, to instruct two or more pupils in a class when there is a difference of a year's work in their advancement results in humiliating and discouraging the less advanced and in making the maturer pupils conceited. Higher learning in the possession of a fellow-man seems to an illiterate person as some-

thing magical, or bordering on the miraculous; he can make combinations of thought which surprise those who are unused to them. The case is worse with the child in school. To him the elevation given by a year's study seems an endowment of nature and not a result of industry. Permanent injury to the pupils is very often occasioned by wrong classification, for not only does the lower suffer from discouragement, but the higher pupil is necessarily injured by not being held to his best. The teacher is perforce obliged to adapt the lesson to the average of the class. This does not give enough work for the advanced pupil, although it gives too much for those below the average. There is not enough demand upon the first to continue the increase of his powers; he becomes indolent and stops growing.

For these reasons classification as above described ought not to be expected in the rural school; it must remain ungraded, and as a result the teacher must resort to individual instruction wherever there are intervals of a year or more in degrees of advancement between pupils, and this is the actual practice in perhaps the majority of such schools. The older pupils at least should have separate grammar, history, and arithmetic lessons.

It is understood by your subcommittee, as a matter of course, that even in a small school of six to ten pupils there may be two or more pupils of sufficiently near stages of progress to form one class—for example, two beginners in arithmetic, grammar, geography, or history. It may be that a dull pupil has already been studying arithmetic, grammar, or history for a quarter or a half year, and that a bright pupil just commencing the study would be able to keep up with him on a review from the beginning of the book; but it would not do to place a dull pupil commencing a study with a bright one who had already a half year's start in it. It often happens that pupils placed in the same class at the beginning of the year separate widely in power to learn new lessons before the middle of the year. In such cases a class should be broken up to prevent the twofold injury, namely, to the bright pupil by assigning him too short lessons, and to the dull pupil by assigning him more than he can well accomplish.

The teacher, even after forming classes in writing, reading, and spelling, has twelve to fifteen lessons to hear in a forenoon and nearly as many more for the afternoon. There is an average of less than ten minutes for each recitation. The ideal of the recitation or class exercise is that the teacher probe to the bottom the pupil's preparation of his lesson and correct bad habits of study. If the pupil fails to master by sufficient industry the details—the facts and external items—the teacher counsels and reproves, requiring more work on the same lesson. If he finds that the details are mastered, the teacher next tests the combinations, the thoughts that the pupil has used in connecting one fact with another and in seeing relations. Facts are connected so as to form a science when each one is made to throw light on every other fact and all explain each. So a lesson is learned properly when the pupil can place each item in its systematic relation to the whole. He must understand the bearings of all. He must think out the interrelations.

Hence it happens that the good teacher is not satisfied with a memoriter recitation of the details of the lesson—still less with a word-for-word rendition of the text-book. Not the mere words of the book, nor even the disconnected facts or details which the words indicate, but to bring out the thought which unites these details and explains them is the main object of the good recitation. But such a recitation requires time. The teacher can not probe the pupil's knowledge in five minutes and correct his bad habits of study—nor in ten minutes. In the necessarily brief recitation of the ungraded school there is barely time to test the pupil's mastery of the external details of the lesson, the mere facts and technical words. It is for this reason more especially that the rural school has been the parent of poor methods of instruction—of parrot memorizing and of learning words instead of things.

At the beginning of this century only one-thirtieth of the inhabitants of the

United States lived in towns of 8,000 people or upward, and more than 80 per per cent of all the public schools were ungraded schools. The question has often been asked how it is that so many able men who became scholars and statesmen and professional men of eminence could have come from schools as poor as the rural school is said to be. Such eminent men as were produced in those times came from the rural school; there were few graduates from graded schools to compete with them. Of the men now living, past the middle age of life, nearly all received their early education in the rural ungraded school, because even as late as 1850 at least 80 per cent of all the public schools were ungraded, there being only 12½ per cent of the population resident in cities. The rural school threw on the pupil the burden of his education. He was obliged to get his knowledge from books, such books as he could come to possess. Bright pupils do pretty well by themselves if given good books and taught how to read and to understand the technique used in the elementary books of mathematics, grammar, and the other liberal arts. Any country boy who acquires a love for books, who has access to the best ones, and studies them with energy will by middle age become a learned man.

In the ideal classified school the teacher has two classes of pupils, each class containing within it pupils substantially at the same stage of advancement. The pupils of a given class recite together in all the branches, and the teacher has a half hour for a lesson and can go into the dynamics or casual relations of the facts and events treated.

Each pupil in a class learns as much from his fellow-pupils as from the teacher direct; for the teacher draws out of the class its store of observations and reflections on the topic of the lesson. He shows up the one-sidedness of the preparation of the individual pupil; some have neglected this point and some that other point. Each has probably neglected something. But, on the other hand, each of the diligent ones has brought forward something new that is valuable to his fellows. Each pupil finds through the recitation of the others that they have seen some things that had escaped his notice, although he supposed that he understood thoroughly the book presentation of the subject. His teacher suggests many new ideas and criticises the one-sidedness of the views of the pupils and also, it may be, of the text-book. All the statements of the book are brought to the test of verification—either through the child's experience or through other authorities. The child thus learns the method of study.

The ideal classified school can teach and does teach proper methods of study; the rural school can not do this effectively in its five or ten minute recitations. It is because of this that wise directors of education have desired the consolidation of small schools into large schools wherever practicable. Two schools of ten each furnish on an average one-half as many recitations if united as they do when separate, owing to the possibility of pairing or classifying pupils of the same degree of advancement. Ten such schools united into one will give 100 pupils, with a possibility of classes of ten each, which can be more efficiently taught than before, because the pupil can learn more in a class than by himself. The class in the hands of a good teacher is a potent instrument for reaching all sides of the pupil's observation and reflection. Again, it is evident that five teachers can teach the 100 pupils united in one school far better than the ten teachers were able to teach them in the ten separate schools. If still further consolidation were possible and 400 pupils were united in one school, the classification might be improved to such a degree that a teacher could easily take the charge of two classes of twenty pupils, and ten teachers could do far better work for each pupil than was done by the forty teachers in the forty small rural schools before consolidation. Hence, economy becomes a great item in what are called "union schools."

Your subcommittee, in this discussion of the advantages of classifying and the corresponding disadvantages of the want of classifying, has assumed that as good

teachers are supplied to the rural schools as to the schools of villages and cities—teachers of experience and skill, teachers of thorough academic and professional training in normal schools. It is assumed that States have made provision for good salaries in these ungraded schools and that the license to teach requires professional training.

It is admitted as a fact, however, that the average rural-school teacher receives a small salary—not more than one-half that of the teacher in the city or large village. It is true, as reported by the subcommittee on maintenance of schools, that some States, notably California, New Jersey, Massachusetts, Rhode Island, and others to a greater or less degree, are providing, by a wise distribution of school money, to secure skillful teachers for these small, ungraded schools. But the evils above described as appertaining to instruction in ungraded schools are of such a character as not to yield to ordinary remedies.

Your subcommittee would call special attention at this point to the evil results that come from the attempt to remedy the defects of the rural school by forcing on it the system of classification found in cities. It is assumed that some of the benefits of the close grading possible in cities will be gained for the rural schools if they can roughly group the whole school into three or four classes. A rural school of thirty pupils, comprising children from 6 to 16 years of age and covering different degrees of progress, from beginners up to those of eight or nine years of schooling, are grouped, let us suppose, into four classes or grades, thus leaving intervals of two or more years of school work between a given group and the next one above it.

Your subcommittee has already pointed out the evils of classifying pupils in such a way as to bring together pupils differing in degree of advancement by intervals of two years. In fact, it has been found in city schools that one year's interval between classes is too much. The greatest danger of the graded-school system in cities comes from holding back bright pupils for the sake of the slower and duller pupils. Next to this is the evil to the dull ones, who are dragged forward at an unnatural rate of progress to keep up to the average rate of the class. The best pupils are engaged in "marking time," while the slowest are constantly spurred forward by teachers and parents to keep with their class, and their school years rendered miserable. Their self-respect is undermined by a false standard, that of mere speed in learning. The "marking time" injures the bright pupil by developing lax habits of study, while the forced marches of the slow pupil tend to destroy his poise of character. It has been found desirable, therefore, in city schools, to make the intervals between classes as small as possible, so as to favor frequent transfers, namely, on the one hand, of bright pupils who are becoming capable of a greater amount of work into a higher class, and, if necessary, of those who are falling behind the average of the class into the next one below. Intervals of a half year are, therefore, adopted in a majority of the progressive city school systems, and many prefer intervals of a quarter of a year where it is practicable to make them, that is, where a large number of pupils makes possible the assignment of a requisite quota for each class. At the request of the subcommittee, Dr. E. E. White, an eminent authority on all that relates to school management, has furnished a statement of his views of classification in the rural school, illustrating them by a programme, which allows twenty-five minutes for each recitation. But the intervals between the classes amount to two years' work, and inasmuch as he expressly provides for capable pupils, letting them "work ahead of their classes," he leaves the question where it is left by the subcommittee, unless the pupils are supposed to do their "advance work" without the teacher's supervision. (Appendix I.)

Your subcommittee would respectfully call attention to the danger of attempting to classify the rural school in imitation of the city school as peculiarly liable to happen in those schools where professionally educated teachers are employed.

The State and city normal schools have very properly laid stress on grading and classification, and on the methods of instruction by classes, and have ignored individual instruction. Their graduates have mostly sought and obtained places in the graded schools of cities and villages. In fact, the graded schools have outbid the rural schools for teachers having professional training. But, with the new movement to secure better teachers for rural schools by larger appropriations from the State, it has happened that many experiments of classification are attempted which result disastrously in the manner described, namely, by demoralizing or destroying the courage and ambition of the exceptionally bright and the exceptionally dull pupils. The charge has been made that such rural schools as adopt a partial grading system are apt to become stifiers of talent by placing a premium on the average scholars and holding back the promising youth of the district.

It is obvious from this that where State normal schools furnish teachers for the rural districts there should be conducted a special inquiry into the influence of the size of the school in determining the uses and the dangers of grading and classifying pupils.

There is no doubt, moreover, that the abuse of classification is the crying evil of the schools of villages and small cities. For the average pupil these village graded schools are uniformly good, but they often work injury to the exceptional pupils and are in this respect sometimes inferior to the ungraded schools in sparsely-settled districts.

Your subcommittee would here explain that the technical terms "grading" and "classification" are often used, as above, to signify the same thing, namely, the dividing of the pupils of a school into groups or classes, each containing children of the same, or substantially the same, degree of advancement. But another meaning is often given to one of these terms. The work of the year, more or less, is also called the work of a grade, and the work of the elementary school, consisting of the first eight years' work, is divided into eight grades. It will be readily understood in this second use of the word "grade" as covering a year's work that a school may be graded, that is to say, its work may be arranged upon a programme of eight grades, each one of which requires a certain modicum of reading, writing, arithmetic, geography, grammar, etc., for a year's work, and yet have only ten or twenty pupils, and perhaps these representing only three or four of the eight grades.

By a graded school, as applied to such a state of things, is meant simply a school whose programme requires a regular sequence of studies and a full quota of studies for each pupil. If a pupil is at a certain degree of advancement in his arithmetic, the programme of the graded system would place him also in a class correspondingly advanced in geography, history, reading, or other studies. But the small rural school has been called "ungraded" because it contains or may contain pupils of all grades, from the lowest to the highest, and consequently obliges the teacher to scatter his teaching force over a wide range of topics. The large school permits specializing by dividing the school in such a way that the pupils of one grade, or perhaps two grades, are taught by one teacher, the next one or two grades by another teacher, etc., permitting each teacher to specialize his work by giving him fewer topics to teach, and consequently insuring longer recitation periods and constant improvement in skill.

It is to be supposed that all schools will be graded in the sense that they will have a course of study, and that pupils will take up their branches of study in due order, and that these studies will be associated, so that a given degree of advancement in one study implies a given degree of advancement in another. What is properly called the correlation of studies presupposes that a certain degree of advancement in arithmetic corresponds to a certain degree of advancement in geography, reading, grammar, and other studies, all of these being determined within limits by the pupil's age. The word "grading," as a synonym for

classification, is freely used by your subcommittee in this report, but it has discussed the topic indicated in the other and less frequent use of the word "grading" in that part of its report which follows, relating to the course of study.

THE COURSE OF STUDY.

Your subcommittee has assumed that the course of study in the rural schools should be substantially the same as that of the city schools. The differences should concern only minor details. It would, therefore, refer here to the report of the committee of fifteen for fuller details, and for the discussion of the grounds for selecting the several branches of the course of study. The course of study of the elementary school, whether urban or rural, should contain those branches which give the child an insight into the physical world and the means of conquering it for human uses, and also an insight into human nature and the motives that control the actions of men. The child should above all be taught how to combine with his fellows to secure reasonable ends. The windows of the soul are to be opened by the five branches of the course of study, thus enabling the youth to see (1) the conditions of inorganic nature by arithmetic and the elements of physics and chemistry; (2) the conditions of organic nature by studying plants and animals, the land, water, and air, and, besides these, the means that man invents and uses to connect each place with the rest of the world—these things belonging to geography. These two "windows" look out upon nature. The three others enable us to see man; (3) literature and art as revealing human nature, arousing pure and high aspirations in the youth, and freeing him from narrow and mean views of life; (4) the study of the structure of language, as found in the several subdivisions of grammar and rhetoric; (5) history, which treats of the greater self—of man as a social whole.

These five branches belong to all schools, for they relate to the substance of humanity and are necessary for entrance upon civilization. Besides arithmetic, geography, literature, grammar, and history, there are collateral branches that each school should include—some of them information studies, such as oral courses in the sciences, in history, and in the arts—others of the nature of disciplines, or arts of skill, such as vocal music, gymnastics, manual training, the art of cooking, and some special attention to the elementary principles of the useful arts practiced in the neighborhood of the school, namely, farming, horticulture, grazing, mining, manufacturing, or the like (Appendices G and H).

In general these collateral branches should relate to the pupil's environment and help him understand the natural features of that environment, as well as the occupations of his fellow-men in the neighborhood. There are two things to understand in this matter of the geography of the environment. First, what it is and how it came to be—its land and water, its mountains and river valleys, its climate and soil, its productions, mineral, vegetable, and animal, and their peculiarities, how they differ from the productions of the rest of the world. Second, the means by which man procures from nature what is useful for himself and others, manufactures it and uses it, or exchanges it with his fellow-men so as to share in the productions of all climes and places, no matter how far distant. If a comparison must be made, this second topic of elementary geography is more important than the study of the natural features of the environment, because it is more immediately useful to the pupil and to the community in which he lives.

Let the pupil beginning the subject of geography commence with what is nearest to his personal and social interests, namely, with the products of the industries of his section. Let his studies go out from these products in two directions; first, to the natural conditions which make these products possible and which furnish in general the raw material; secondly, in the direction of the purpose of this, the uses made of it, the things produced, the needs and wants of his fellow-men near and

far; and the productions of the other parts of the world which are needed in his section to complete the supply of articles for food, clothing, shelter, protection, and culture. These items, including natural production and the human occupations of manufacture and exchange, may be said to be the chief theme of geography as it should be taught in the elementary schools. But the home environment is also to be kept in mind by the teacher throughout the entire course. Arithmetic should gain concreteness of application by its use in dealing with home problems. Literature should be pointed and applied, so far as may be without becoming provincial, to the pupil's environment; and so the other branches—history, and even grammar—should be brought home to the pupil's knowledge or experience in the same way. The pupil should have prepared for his study a list of the chief provincialisms of speech to which his section is addicted, and to the peculiarities of pronunciation in which his neighborhood departs from the national or international standard of usage.

The committee of fifteen has already advanced the opinion that the industrial and commercial idea is the central idea in the study of geography in the elementary schools. It leads directly to the natural elements of difference in climate, soil, productions, races of men, religion, political status, and occupation of the inhabitants, and it explains how these differences have arisen in some measure through cosmic and geological influences. It should be the teacher's object to make the pupil understand, just as early as his growing capacity admits, the peculiarities of his habitat, leading him to study the land and water formations in his neighborhood, and giving him power to recognize in the visible landscape about him the invisible forces that worked in the past, and still are at work in the present, molding these shapes and forms. On the basis of this knowledge of the elements of difference produced by nature in soil, climate, and configuration of the landscape, he should explain the grounds and reasons for the counter process of civilization which struggles to overcome these differences by bridging the rivers and tunneling the mountains—by using steamboat and railroad so as to unite each particular habitat with the rest of the world. He should see how man adapts to his needs the climate of each place by creating for himself a comfortable temperature, using for this purpose clothing and shelter, as well as fuels of wood and coal or derived from oils and gases, to protect from cold, and on the other hand utilizing ice or power fans, and creating easy access to summer dwellings on the heights of mountains or at the seashore, to mitigate the heat. He turns the soil into a laboratory, correcting its lacks and deficiencies by adding what is necessary to produce the crop which he desires. He naturalizes the useful plants and animals of all climes in his own habitat. It is evident that the details of the process by which differences of soil, climate, and production arise, important as these are, should not be allowed to occupy so much of the pupil's time that he neglects to study the counter process of industry and commerce by which man unites all parts of the earth to his habitat, and progressively overcomes the obstacles to civilization by making climate and soil to suit himself wherever he wishes.

To restate this important point in a word, it is true that the deeper inquiry into the process of continent formation, the physical struggle between the process of the upheaving or upbuilding of continents, and that of their obliteration by air and water; the explanation of the mountains, valleys and plains, islands, volcanic action, the winds, the rain distribution, is indispensable to a comprehension of the physical environment. But the study of the cities, their location, the purposes they serve as collecting, manufacturing, and distributing centers, leads most directly to the immediate purpose of geography in the elementary school, for it is the study of that civilization in which the pupil lives and moves and has his being.

Keeping this human standpoint in view all the time as a permanent interest, the inquiry into causes and conditions should proceed concentrically from the pupil's use of food and clothing to the sources of the raw materials, the methods

of their production, and the climatic, geologic, and other reasons that explain their location and their growth. It is important in this as in all matters of school instruction to avoid one-sidedness. Although the human factor should receive the most emphasis, special care should be exercised lest the nature factor should be neglected.

Your subcommittee would refer to the discussion of this subject under the head of "Geography" in the report of the committee of fifteen for further illustration.

There is not much use in requiring instruction in branches not yet reduced to pedagogic form. It is necessary that matters taught should be so systematized for school use as to admit of arrangement in a progressive series of lessons, the first of which alone would be useful if no second lesson followed, and the subsequent lessons each useful if the pupil studied none of the following.

Each lesson when arranged in a pedagogic form leads up to the following lesson and makes it easy to grasp, just as each stair makes the next one easy to climb. For example, the first lesson in cookery is an exercise in accurate measurement by spoonfuls and cupfuls, etc., and calculated not only to aid in the next lesson and make it possible, but also to be of use through life in the kitchen. Concerted efforts are being made in agricultural colleges to reduce to pedagogic form the arts of the farm, the garden, and the forest.

THE PROGRAMME OF STUDIES.

Your subcommittee deems it important to call attention again in this place to the prevalence of a misconception in regard to the relation of the course of study to the system of grading and classification. Every school, whether ungraded or graded, should have a course of study minutely arranged, so as to show the average or reasonable rate of progress of the pupil of a given age and advancement in the work of the school; but, as has already been shown, it is not required that the school shall contain classes in each and all of these grades, nor, indeed, classes at any given stage of progress in the course of study as laid down for any particular quarter or term of the year. Above all, it must be understood that in laying down the quarters or other divisions of a grade or year's work it is not to be expected or desired that the pupils entering school at the beginning of the school year in the fall should commence at the beginning of any grade's work. If a class consisting of two or more individuals (or of one individual only) left off the previous year in the third quarter's work of the fourth grade, it should begin its work after vacation at the point where it left off, unless there are special reasons which require a review of some portions of the work.

The course of study is the measuring rod or scale which is used to determine at what point in the eight years' work of the elementary course a pupil has arrived. It should not be used as the Procrustean bed on which to stretch the work of the school in order to give it uniformity. It has happened not infrequently in the past that upon the first adoption of the graded system the superintendent of city schools held annual examinations on the completion of the work of the grade, and for this purpose insisted upon the unreasonable requirement that all of the pupils in the school should have begun the work of a grade on the first day of the year and should be expected to finish the grade work in the fourth quarter of the year. This was said to be for convenience of promotion—all pupils leaving the work of one grade and passing to the next were said to be promoted. This fiction has effected serious injuries in city schools. The apparent reason for such a system was the convenience of the superintendent who desired to make only one set of questions for each grade, and hold his examinations all at one time. If he had adopted a plan of preparing an examination for any class of pupils at the time when they should have completed the work of the grade (whether in the first, second, third, or fourth quarter), such a system need not have existed. The false

idea of promotion has also been the source of great evils. When a pupil has finished the work laid down in the course of study for any grade, he should begin the work of the succeeding grade at once, and it is not necessary to have any special examination. The class teacher is supposed to examine her pupils from day to day, for each recitation is an examination revealing the pupil's understanding not only of the day's work but of his previous lessons; and the principal of the school is supposed to be well acquainted with the progress of his pupils. It is not necessary, therefore, to hold a general examination on the work of the grade if the class teacher and the supervising principal have performed their duty.

It is understood, too, that there should be much written work in the school, but that it should not as a rule take the form of competitive examinations. There is no other exercise in the school more valuable than that of written expression, but this should be limited chiefly to the review work of the pupil. The teacher, for illustration, should prepare questions at the close of the week on the previous five or six days' work, such questions as bring out the most essential points and the principles which connect the details that have been studied. The pupil should be permitted to sit down by himself with plenty of time before him to write out his answers to these probing questions. By this means he learns gradually to collect his thoughts, and will do more thinking in connection with his written examination than in any other test or study in his school course. The written examination should not be postponed till the end of the year or to the end of the quarter, but should be a matter of at least weekly occurrence. It should be written work of a review character rather than examination of a competitive character.

While the course of study for the elementary school will cover eight years and be subdivided so as to show quarterly, semiannual, or other stated progress, as already said, it will not be expected that the rural school with its 10 or 20 pupils will have each and every grade represented; perhaps, for instance, there will be three pupils in the first grade, two in the second grade, one in the third grade, none in the fourth grade, two in the fifth grade, none in the sixth and seventh, and two in the eighth grade.

Your subcommittee assumes likewise that the discipline of the rural school should be strict though mild, like that of the city school. The fundamental school virtues of regularity, punctuality, and industry are auxiliary to moral virtues and form together a training of the will which is of great importance in producing the future good citizen. It must not be thought that, because a school is small, therefore the discipline is of less importance. The formation of habits of order and of respect for the rights of the social whole is necessary for the good citizen, whether of country or town.

REMEDIES FOR THE EVILS OF THE RURAL SCHOOL.

Your subcommittee would here point out that some of the evils of the rural school are due to its nonsocial character, its inability to furnish to each of its pupils that educative influence that comes from association with numbers of the same age and the same degree of advancement. The rural school furnishes only a few companions to the youth, and those either above him or below him in grade of progress in studies. The remedy for the evils of the ungraded school are suggested by this very feature or characteristic. Radical remedies in this case must all contain some device to bring together pupils of different districts and bring into wholesome competition with one another the pupils of the same grade of advancement.

Transportation to central schools.—The collection of pupils into larger units than the district school furnishes may be accomplished under favorable circumstances by transporting at State or local expense all the pupils of the small rural districts

to a central graded school and abolishing the small ungraded school. This is the radical and effective measure which is to do great good in many sections of each State. As shown already by the subcommittee on the maintenance of schools, Massachusetts, in which the plan began under the town superintendent of Concord, Mr. John B. Tileston (about the year 1878 in Concord, or even earlier in the town of Quincy, see Appendix F), paid in 1894-95 the sum of $76,608 for the transportation of children from small rural schools to central graded schools—213 towns out of a total of 353 towns and cities using this plan to a greater or less extent, and securing the twofold result of economy in money and the substitution of graded for ungraded schools. The spread of this plan to Maine, Vermont, New Hampshire, Connecticut, Rhode Island, New Jersey, Ohio, and some other States (see Report of Bureau of Education for 1894-95, pp. 1469-1482) demonstrates its practicability. Experiments with this plan have already suggested improvements, as in the Kingsville experiment in Ohio, where the transportation reached in all cases the homes of the pupils, and yet reduced the cost of tuition from $22.75 to $12.25 a year for each of the 50 pupils brought to the central school from the outlying districts.

Improvement of roads.—Wherever this plan of abolishing the small ungraded school is practicable it is by far the best remedy to be applied.

But there will remain large numbers of small ungraded rural schools in which the plan of transportation is not feasible by reason of great distances and poor roads. The Agricultural Department is seconding the efforts of many States to improve roads in rural districts. In many places road improvement is a necessary condition previous to the betterment of rural schools.

Special appropriations for small rural schools.—The device of securing skilled and professionally trained teachers by providing, as in California, a sufficient salary for each district, no matter how few its pupils (see Appendix C), has already been described by another subcommittee (that on maintenance). It is undoubtedly a wise measure, provided it does not hinder the consolidation of districts through the adoption of the Massachusetts plan. If it works to preserve the small ungraded school in places where consolidation is feasible, it will in the end be an injury to the cause of rural schools. Your subcommittee therefore ventures to call attention to the importance of adopting such laws as are operative in California, New Jersey, Massachusetts, and New York for the better remuneration of rural-school teachers, but with a proviso that makes it a pecuniary advantage to a town to abolish its outlying ungraded schools and furnish transportation to a central school.

Concentration of the higher grades of pupils.—Where transportation of the whole school is not feasible, it sometimes happens that the teaching may be very much improved by the transfer of two or three of the pupils of the higher grades who consume very much of the teacher's time. By transportation of these two or three pupils to the central school the teacher thus relieved may find time for much better instruction of the pupils in the lower grades who remain under his charge.

School exercises at the town or county centers.—For the small ungraded schools that can not be abolished, perhaps one-third of all the schools in the United States at the present time, your subcommittee suggests the provision of occasional meetings at town centers or county centers, perhaps twice a year or oftener, under the direction of township, union township, or county superintendents, as the case may be. The meeting should have as its primary purpose the bringing together of advanced pupils—say sixth to ninth years' work for examination and comparison, the examinations to be chiefly written. Certificates should be given to those who complete the elementary course of eight years as a whole or in any one of its branches, permitting a pupil who passes in one branch this year, say in grammer or history, to pass in another branch at a subsequent examination whenever he

presents himself. These examinations have been in operation in several counties of New Jersey for nearly twenty years.

This plan has an interesting and profitable illustration of many of its features in the operation of the Boxwell law in Ohio. (State School Commissioner Corson, Report 1895–96.) It was also carried out years ago in many particulars by Superintendent Wade in West Virginia.

The proper use of competitive examinations.—It is understood by your subcommittee that the prejudice against competitive examinations is well grounded. It often happens that schools are subjected to mere mechanical drill in order to secure a higher per cent in this sort of examination. High per cents can not be obtained by entire classes upon work which requires not only a knowledge of details, but a knowledge of the causal relations underlying them. Your subcommittee desires to say that it does not recommend indiscriminate competitive examinations, but that it recommends written work and examinations which test the thinking ability of the pupil and lead him to considerate inquiries and accurate statements. High per cents on anything except mechanical work, such as spelling, the multiplication table, the tables of weights and measures, and paradigms, are not desirable.

The plan of township and county union exercises of rural schools above described obviously includes the good feature of social interconnection, each pupil of the remote districts working consciously in combination with many others toward a common end, and all the pupils stimulated, both in school and out of it, by this social motive.

Promotion of home reading.—The excellence of the Chautauquan plan for the promotion of home study lies in the same feature. Each reader is stimulated and encouraged by the consciousness that he is working on a task common to the endeavors of a vast multitude. The task is dignified and ennobled by such social participation. The youth in the rural district is by this plan to be made a home student, and his education is thus to be extended beyond the school. He may have obtained his first recognition in the township examination while he was a member of a rural school. He is an object of semiannual inquiry on the part of the township or county superintendent for years afterwards. Each new teacher that comes to the rural school is charged by the superintendent with the duty of looking up the young men and young women who made a record in the central examinations, and inquiry is made after their continued reading and study. This in itself will be a powerful influence to cause young people to continue self-culture by studying a prescribed series of books in years subsequent to the school period. It will add dignity and self-respect to the rural-school teacher who is charged with the work of making friendly inquiry into this school extension and of offering help in case of application from any of the parties interested.

Reviewing studies.—The rural school with its five-minute or ten-minute recitations can not do much in the way of reviewing previous lessons. The good teacher in a graded school carries on from day to day a review of previous lessons. He gathers up and connects with the lesson of the day all the essential threads that bind it to what has gone before. It is this work of reviewing that will be assisted by the occasional examinations at the township center.

Moreover, the old evil of the rural school, that of having all pupils begin at the beginning of the book at the commencement of each annual term, will be removed, for the superintendent will have a record of the standing of the advanced pupils and will require a report from the new teacher as to their programme of study.

This plan also points to the utility of more written work in the rural school. A set of questions prepared beforehand and given to a pupil at the close of the week, as above recommended, will test not only his knowledge of the superficial details of his week's work, but also of his understanding of their deeper connections and principles, as no oral recitation could be made to do.

School extension.—In this connection another branch of what is called "school extension" or "university extension" is practicable. Home reading can be managed from the same center, namely, the rural school. Everything that adds social importance to the rural teacher may be of service. It is evident that those pupils who have graduated from the public school and have entered upon the business of life may profitably carry on useful courses of reading in the various departments of literature and art, science, and history. The township or union township superintendent, in conjunction with the county superintendent or State superintendent, should set into operation as far as possible courses of home reading, employing the aid of the rural-school teachers to carry this into effect. A record containing the names of the persons who have undertaken home reading, the names of the books completed, and the dates of such completion will form an interesting record. This home reading, moreover, should have its social gatherings in which there are discussions of the contents of particular books that are read. For this purpose the township superintendent or the county superintendent may select specially well-fitted persons who shall present analyses of the books and discussions of their contents. It is desirable that the course of home reading shall not be one-sided, but shall move in each of the three directions: literature, including poetry and prose; science, looking toward the organic and inorganic kingdoms of nature, the plant, the animal, and the details of matter and force; and toward archæology, ethnology, and sociology, and politics, history, biography, and art. One must not be altogether dissatisfied if it is found that the novel is the chief book in demand, especially in the first five years of the home-reading circle. In our day the novel discusses every question of history, politics, sociology, and natural science. The old-fashioned novel which describes manners has its great use, too, in the fact that it gives to the people of whom we are speaking, the people of the rural districts, a ready knowledge of manners and customs of polite society. In this respect it is sometimes more useful than books of science and history.

Lancasterian or monitorial plan.—The topic of written work suggests a further topic of great importance in the rural schools, namely, that of the occasional employment of older pupils in the work of supervising the exercises of less advanced pupils—a committee of two or three pupils to examine and mark the papers written by those studying geography; a monitor assigned for some hour in the day to inquire into the work of a backward or dull pupil who has reached a difficult place in arithmetic; a similar assignment of a pupil to help another in a grammar lesson or a history lesson; these are cases where the monitorial or Lancasterian system may have greater or less utility. It cultivates directive power and self-respect in a pupil to be called to the aid of the teacher. But the dangers of it are well known. No weak disciplinarian should try the monitorial system. On the other hand, every strong disciplinarian in the ungraded school can use some features of it to advantage.

The bane of the Lancasterian system was its use to furnish cheap assistant teachers in graded schools. It resulted in bringing into the schools a class of so-called "pupil teachers," educational novices in the place of experienced and professionally trained teachers who ought to be everywhere employed in graded schools. Limited entirely to ungraded schools and to teachers with disciplinary power, the older pupils may profitably be employed to help in the work of the school. But they should not take up any work continuously. It should all be occasional, inasmuch as every thread of the school work must come under the eye of the schoolmaster frequently—daily, or nearly as often. If he has asked an older pupil to explain a point in arithmetic to a dull pupil, the latter will show the degree of efficiency of that help in the first recitation after it.

Another rule for the guidance of the teacher is: Never to employ a monitor

unless such assignment of work is useful both to the pupils taught and to the pupil teacher.

A teacher may gain time needed for assistance of the advanced pupils in some important study by requiring in advance the assistance of these pupils in some of the following forms:

(1) Marking examination papers.

(2) Helping pupils over some difficulty in arithmetic, grammar, or other branch having strict logical sequence in its topics.

(3) In explaining the thought of a reading lesson to a backward pupil.

The effort of one pupil to explain to another a difficult passage of literature is one of the most profitable of all school exercises. There will undoubtedly be crudities in the explanation, but this will all come out under the teacher's subsequent tests, and the exercises will increase in profit through the final explanation given by the teacher.

(4) In assisting to test mere memory work on the part of a pupil, as in the case of the spelling of difficult words, the learning of paradigms in grammar, the learning of the required tables of weights and measures, the multiplication table, etc., or in any other necessary data that have to be fixed in the memory. In general, what is nearest to mechanical work may be supervised at times by monitors, and monitors may be useful in assisting in the preparation of thought lessons that are to come later before the schoolmaster, as, in the example given, the getting out of the thought of a reading lesson, or even of a history lesson.

In conclusion your subcommittee would lay chief stress on the function of school extension, above sketched in outline, as the most profitable line of work for the improvement of the rural school—both pupils and teachers.

WILLIAM T. HARRIS, *Chairman.*
ADDISON B. POLAND.
LLOYD E. WOLFE.

Mr. Poland, while concurring in most particulars, desires to add the following statement:

While I concur most heartily in nearly all of the recommendations made by the subcommittee on course of study, etc., I feel compelled to state that, in my opinion, the report somewhat exaggerates the difficulties and dangers of attempting to classify pupils in rural schools. It fails to discriminate between rural schools of ten pupils each and schools of a larger number, say thirty to sixty pupils each.

The general argument is based upon conditions that exist in a "school with ten pupils of ages from 5 to 15 years;" and the conclusion drawn is that "for these reasons classification as above described ought not to be expected in the (any) rural schools."

The conclusion, it seems to me, is altogether too general. My own observation of rural schools in the States of Massachusetts, New York, and New Jersey has led me to believe that their efficiency as a rule is in direct ratio to their wise and careful gradation; that, in fact, the best graded schools are the most efficient. I am speaking, of course, of rural schools containing twenty-five pupils and upward where partial grading at least is generally believed to be practicable. Grant all the cases of individual hardship that the report truly affirms of misgraded pupils, yet the total loss of efficiency is immeasurably less than where no grading is attempted. Economy of teacher's time, longer recitation period, class emulation, etc., more than offset the disadvantage, often only theoretic, of a pupil's working in advance of his point of "maximum efficiency."

I am not, therefore, in full harmony with the report, in so far as it may have the effect to discourage teachers from attempting to classify pupils whenever and wherever practicable.

A. B. POLAND.

Mr. Wolfe, while agreeing in many points with Mr. Harris, desires to make the following statement:

Perhaps my opinion may be characterized as explanatory or supplementary rather than dissenting. Believing with Dr. Harris that the chief aim of the report of the committee of twelve is to provoke thought, I make this contribution to that end. Complete unanimity no more exists among the members of this committee than among the great army of teachers for whom the report is prepared; nor is such unanimity desirable. The subject will be treated under the following heads:

1. The present condition and trend of rural-school grading and classification in the States of the Union. 2. Dr. Harris's plea for individual instruction rather than the instruction (in the same class) of pupils who are more than one year apart in their advancement. 3. The underlying pedagogic principles that seem to justify Dr. Harris in opposing the doctrine of his report to a body of opinion on classification and grading which is gathering volume and momentum with each decade. 4. Objections to the doctrine of the report.

1. Recent decades have witnessed a strong movement in many of the States of the Union to model the rural-school course of study, grading, and classification after the ideal of the city graded school. Several States prepare, publish, and distribute State courses of study for rural schools, and send out, at stated times, uniform examination questions prepared with reference to the course of study and the system of grading and classification set forth therein. In other States the county school authorities issue the rural-school course of study. In still other States the school journals and associations hold up the grading and classification of rural schools as an ideal to be obtained in the near future.

2. The burden of Dr. Harris's report is: "Be ye not unequally yoked together." Just here a word of explanation of the expression "the ideal of the city graded school." This ideal is a course of study divided into at least eight yearly divisions or grades of work, the pupils of the school being divided into eight corresponding divisions or grades. A school is graded when the pupils of a certain year or grade are pursuing the work of a corresponding year or grade in all the branches. It is, therefore, evident that the word "grade" has two meanings—a grade of work and a grade of pupils. All pupils who are graded are classified, unless there be but one pupil to the grade. But all pupils who are classified are not necessarily graded. A pupil without classmates is graded when he pursues all the work of the corresponding grade, and yet he can not be said to be classified. Pupils may be grouped in classes, and thus be classified, and yet not be graded, because they may be pursuing work of different grades. Dr. Harris is not opposed to a course of study for rural schools, nor to dividing that course of study into eight divisions or grades of work, nor yet to grouping pupils into classes or grades, provided classmates are not more than a year apart in their advancement. But most rural-school courses of study necessitate the grouping of the pupils of the fifth and sixth years of advancement into one grade; also, the grouping of the pupils of the seventh and eighth years into another grade. It thus happens that not only are pupils two years apart in their advancement yoked together in the same class and grade, but that, on alternate years, they are obliged to study the sixth year's work before the fifth, and the eighth before the seventh. It will thus readily be seen that the main thought of Dr. Harris's report is a standing protest against the grading and classification of pupils in the rural school as now practiced in many of the States.

3. We are now to inquire what pedagogic principles can be invoked to justify Dr. Harris in throwing the whole weight of his influence against the evolution of the ungraded country school into the graded school. And first, we must bear in mind that the subject of the report of Dr. Harris is "Instruction and discipline in the rural schools." First, efficient instruction must be adapted to the capacity

of the learner; otherwise it can not be grasped and assimilated. Second, other things being equal, instruction is more efficient when given to pupils associated in classes than when given to individual pupils. Not only does a pupil gain much information from his classmates during a recitation, but the recitation gives him an insight into the individual capacities and peculiarities of those among whom he is to succeed or fail in professional or business life. Third, efficient instruction requires a reasonable length of time for a class exercise. In a city graded school, with at least one teacher for each grade of work, the three principles—adaptation of instruction to the capacity of the learner, grouping of pupils into classes, and a reasonable time for recitation—can be conserved. But in a rural school with one teacher, to maintain one of these principles is to sacrifice another. The principle of the adaptation of instruction to capacity can be adhered to by dividing the pupils into eight grades of advancement; but such division gives a minimum time for recitation and a minimum association of pupils. If, however, pupils of the third and fourth, fifth and sixth, seventh and eighth years of advancement be grouped into three corresponding grades, we secure a longer time for recitation and a larger measure of association, but we violate the principle of adaptation of instruction to capacity, thus associating, in the same grade and class, pupils two years apart in their advancement. It thus appears that the problem of the most efficient instruction in a rural school with one teacher is one of maxima and minima. The principle of adaptation of instruction to capacity forever antagonizes the other two. A maximum adherence to it means a minimum adherence to the other two, and vice versa. Perfect adaptation of instruction to capacity would necessitate a grade for each pupil. Dr. Harris's report shows that he feels that, when pupils one year apart in advancement have been grouped in the same grade, this great principle of adaptation of instruction to capacity has been strained to its utmost limit, and that any sacrifice thereafter must come from other antagonistic and minor principles. His report throughout shows that he considers adaptation of instruction to capacity the paramount and controlling principle; and the fact that he has made this the burden of his report shows with what trained acumen he has brushed aside the trivial and subsidiary, and has laid grasp upon the vital and fundamental.

A still more universal principle underlies this valuable report. It is this: That the success of an institution of any kind—political, religious, economic, educational—depends upon its adaptation to its environment. A republic is, no doubt, abstractly the best form of government; but equally true is it that, under certain environment, an aristocracy or a monarchy is better than a republic. I take it, then, that Dr. Harris has been a spectator of this evolution of the rural school, with its peculiar environment, into the city graded school, with a very different environment, till he has said to himself, "This is a forced and artificial evolution." Having arrived at the conviction that the rural school with one teacher can not without injury be metamorphosed into a graded school, Dr. Harris addresses himself to the problem of changing the present rural school conditions, (1) through transportation of pupils and (2) through pupil-teachers. Now, this goes to the very heart of the question, for, through the transportation of pupils to central schools, the rural school conditions are transformed into city school conditions, and instruction can then proceed in harmony with the three principles above discussed. Or, if pupil-teachers are employed, or if the pupils of the higher grades—fifth, sixth, seventh, and eighth, or seventh and eighth only—be transported, the rural school condition will be in a measure removed and instruction can proceed more in harmony with these principles. It is true that transportation of pupils now seems practicable only in a small portion of the territory of the United States, and that pupil-teaching meets with but little favor among rural-school teachers and pupils; but a careful study of the report of Dr. Harris will no doubt lead to a larger use of pupil-teachers and a much wider extension of pupil transportation,

It, therefore, follows that the reorganization consequent upon transforming the four-teacher school into the one-teacher school would bring some pupils into classes better suited to their abilities than the classes to which the graded system had assigned them, thus bringing about a classification more in harmony with the principle of adaptation of instruction to the capacity of the learner. Classification and its correlative principle of harmonious development are the corner stone of the rural school; grading and its correlative principle of symmetrical development are equally fundamental to the city school. In a graded school the pupil is assigned to classes belonging to one grade only; in the country school he is assigned to classes adapted to his capacity, regardless of the number of grades represented by these classes. I institute no comparison here as to the relative merits of the principles—harmonious development and symmetrical development—but simply state the fact of their relations respectively to the city and rural schools.

If practical adaptation of instruction to the capacity of the pupil were really attainable in the graded school, I should hesitate to recommend a classification that would group in one class pupils more than a year apart in their advancement. But such adaptation is largely ideal and theoretical. However well the school be graded, the strongest pupils and the weakest are separated by a long distance in the character or grade of their work. Whether in the primary, the grammar, the high school, the college, or the university, a certain per cent of the students do most of the highest order of work. These strongest pupils discover and develop the deepest relations. The weaker pupils soon learn to repeat the stereotyped expressions of these relations, and to store them away in their memories to be fished forth at stated intervals by the written test. The Apostle Paul, that he might not offend his brother, would eat no more flesh while the world stood; but a large per cent of the students of all grades, not from fear of offending their brother, but from their very mental constitutions, abstain, with equal fidelity, from the strongest mental diet. I can select, at random, one-half the pupils from grades 6 and 7 of a city school, and put them to studying, indifferently, North America, South America, Europe, or Asia, and the former leaders in grades 6 and 7, respectively, will still lead. What is true of geography is true of history, civil government, physiology, spelling and reading, and, in a measure, of grammar and arithmetic. Certain pupils are mentally built for accuracy, clearness, depth, and power; others, for relative inaccuracy, obscurity, shallowness, and weakness. A rule requiring, as a condition of promotion, that all pupils of any certain grade should do as high an order of work as is being done by some of the pupils of that grade would virtually stop the wheels of promotion. Many of the pupils would never reach a higher grade; many others would do so only after repeated attempts and failures.

The gist of Dr. Harris's objection to grouping pupils who are more than a year apart in their advancement is that the more advanced pupils will be kept marking time, while the less advanced will be dragged along at an unnatural rate. My answer is that the stronger pupils will do the higher order of thinking, just as they always do, while the weaker pupils will do the lower order of thinking, as they always do, getting some knowledge from the books, some from the teacher, and some from their stronger classmates. The rural school has the advantage over the city school in that its pupils learn much from the recitation of classes to which they do not belong. In a graded school the walls of the schoolroom shut pupils out from what is being recited in other grades. In a rural school the pupil can listen to the recitation of any grade. You tell me that this is absorption, that the pupil gets this outside knowledge at the expense of the preparation of his own lessons, and that the practice of listening to other recitations militates against the principle that a great aim in education is to learn to master the printed page; but it is nevertheless the testimony of many of our greatest educators that the knowledge thus obtained by them in the country school was invaluable. The mind has

strange and subtle methods of threading its way to knowledge, not always in harmony with the pedagogue's theory. What teacher in arithmetic (who has had the courage, temporarily at least, to lay aside his cut and dried solution formulæ) has not been surprised and delighted at the ingenious methods different pupils have of solving problems? What master of the topical method in history, civil government, or literature has not marveled at the rich relations revealed by pupils when left free to take their own initiative? A nation does not postpone its entrance upon a career of republican government till all its members are ready for self-government. The members of a church are not of equal intellectual or spiritual caliber, nor are the members of a family; yet they are associated in one class—the state, the church, the family. In actual life, persons of all degrees of advancement behold alike the same procession of the heavens, the same succession of seasons, the same world happenings; but all do not get the same kind and amount of information from the marshaling of the constellations, the budding and fruiting of spring and summer, and the drama of events daily unfolding. I grant that the examples above given are not identical with the thing to be exemplified, but they present important elements of similarity. Finally, I am fully convinced that the rural school conditions necessitate a departure from the doctrine so ably laid down by Dr. Harris, and I believe principles can be found to justify such departure. Whether or not I have found these principles and set them forth in this supplementary report is another question.

L. E. WOLFE.

APPENDIXES.[1]

[1] The appendixes are not reprinted, but a list of them is here given for reference.

CHAPTER XVIII.

ENTRANCE REQUIREMENTS FOR ENGINEERING COLLEGES.

At the Buffalo meeting of the Society for the Promotion of Engineering Education, in August, 1896, the committee on entrance requirements of engineering colleges presented a report giving the results of their investigations.

The committee was composed of the following members: F. O. Marvin, Mansfield Merriman, J. P. Jackson, J. J. Flather, and H. W. Tyler.

In their report the committee adopted the following classification of colleges, which was not based upon the relative general merits or standing of the colleges, but had reference solely to their entrance requirements:

Class A. Those colleges whose requirements for admission include at least algebra through quadratics, plane geometry, solid geometry or plane trigonometry, one year of foreign language, and moderately high requirements in English. (31 colleges.)

Class B. Those colleges of the remaining list whose requirements include algebra through quadratics and plane geometry. (33 colleges.)

Class C. Those colleges whose requirements in mathematics are lower than algebra through quadratics and plane geometry. (25 colleges.)

Class D. Those colleges that offer no courses in engineering as such, but do work analogous to that of an engineering college, generally under the head of mechanic arts. Many of them will undoubtedly develop into genuine engineering colleges. A few of them now give engineering work in a fifth or post-graduate year. (18 colleges.)

Existing requirements.—The requirements for admission to the 89 colleges of Classes A, B, and C are given in the following table in detail for the purpose of showing their great range and variety. The data have been taken almost entirely from the catalogues of 1895, supplemented by information gained by the committee through circulars of inquiry and through correspondence.

Subjects required for admission by 89 colleges giving engineering courses and the number of colleges requiring each.

Entrance examinations v. admission by certificate.—The following table gives the practice of 85 engineering colleges with regard to admission by certificates,[1] in lieu of examination:

Colleges which—	Class A.	Class B.	Class C.	Class D.	Total.
Do not accept certificates	6	2	2	2	12
Accept certificates to a small extent	3	5	2	2	12
Accept certificates to some undefined extent	5	10	8	2	25
Accept certificates to a large extent	14	13	8	1	36
Total					85

[1] In the original report the colleges in this connection are given by name in detail.

The replies to the inquiries of the committee tended to show that nearly every college is satisfied with its own plan of admission. The report goes on to say:

There are 21 colleges that seem to have fair regulations governing admission by certificate, though there are very few that publish their rules in detail or that have given them in detail to the committee if they exist. The University of California has one of the best and most complete systems. The scheme includes the following points, viz:

1. Application for accrediting to be on a special blank, showing the subjects on which the school seeks to be accredited, the names of teachers and the subjects taught by them, the number of pupils in each grade, length of school year and terms, etc., and accompanied by sets of actual examination papers and the course of study.

2. Visitation of school by a faculty committee, whose favorable report is essential.

3. Application for accrediting must be renewed annually. Inspection is annual also.

4. Schools are notified of being accredited on special blanks, showing the requirements for different university courses, the courses for which the school may prepare, and the subjects for which they can write certificates.

5. Certificate signed by the principal shows the graduation of the candidate, the list of subjects in each of which the principal recommends, and the course the candidate desires to enter.

6. Lack of above recommendation in any subject to be counted a failure.

7. More than two failures, or one failure and two conditions, or three conditions prevents admission.

8. Failure in algebra and geometry or physics and chemistry prevents admission.

9. Certificates are accepted by a committee, but can only be rejected by the academic council.

10. Besides above-mentioned blanks, the university issues departmental circulars as occasion arises containing suggestions as to preparatory work. Also an admission circular of 120 pages containing the following matter: A few pages of general information; extended description of all subjects included in any requirements; requirements for the different university courses; time, place, and order of entrance examinations; rules governing examinations; rules for accrediting schools; suggestions regarding preparation for the university; samples of questions previously used for entrance examinations.

11. The university holds conferences on secondary education with high schools and normal schools.

Professor Christy speaks well of the working of this system and says that it is the result of a good many years of persistent effort on the part of the university.

The University of Michigan has a similar plan, accrediting schools for three years, using four circulars. No. 1, the circular of instructions to the school applying. No. 2, the application showing enrollment, length of course and year, size of library, amount of apparatus and museum collections, character of laboratories, etc., also asking for further information concerning teachers, their length of service, where educated, subjects taught; concerning studies, the text used, the ground covered, time given in weeks and hours per week, and in what grade the subject is taught. No. 3, report of inspecting committee, including statistics of the school and its facilities, a statement of studies pursued, text-books used, time given, grade of work, an estimate of the efficiency of each teacher, and a recommendation that graduates be admitted to certain indicated university courses. The inspection may be made by others than members of the faculty, the university delegating its authority to some selected person or persons. No. 4, the certificate showing graduation and detailed list of subjects.

The School of Practical Science, at Toronto, admits the largest part of its stu-

dents on a government certificate to the effect that the candidate has passed the "high school leaving examination." In the Province of Ontario the government conducts these public school examinations.

In New York and adjacent States the certificates of the New York regents are taken by some colleges for the ground covered.

Not all of the 21 colleges mentioned above have as complete a method as California or Michigan, but they all require considerably more on the part of a school seeking to be accredited than the mere condition of "being satisfactory to the faculty."

In expressing an opinion as to the present working of the certificate plan, or its extension, many of the committee's correspondents are epigrammatic or answer its questions by a short yes or no. But one can gather from the general character of the replies that the objections raised are in many cases due to dissatisfaction, not so much with the present system as with its working, and that those favoring the system do so because of its applicability to existing conditions and its inherent advantages.

Uniformity of requirements.—The tabulation below gives a summary of the replies under this head:

Class.	A.	B.	C.	D.	Total.
Desirable to some extent	17	18	10	4	49
Not desirable	6	5	3	1	15
Practicable to some extent	8	14	4	2	28
Not practicable	8	9	13	2	32

The replies as a whole are quite decidedly favorable to the abstract idea of uniformity, though the belief in its practicability is not so general. Here again the answers, many of them, were confined to monosyllables or were given in more or less uncertain terms. This is a very natural result, because no definite plan of action was presented for consideration and because of a lack of practical experience with any scheme involving it.

General statement of principles.—Before the committee formulated its conclusions, attention was directed to certain general principles, some of which were assumed by the committee, while others form the basis of replies received. These principles and the conclusions of the committee are stated as follows:

1. In its circulars of inquiry the committee expressed its opinion that "preparation for scientific or other colleges is an essentially secondary function of the great body of high schools of the country, and that entrance requirements should be, so far as necessary, adapted to the capacity of any high school of thorough methods and high standards."

2. The primary object of entrance examinations or other requirements is to determine whether each candidate for admission has attained a certain standard, of development on the one hand, of information on the other, fitting him to undertake the work of the particular college in question.

3. The secondary effect of entrance requirements in particular subjects is a tendency on the part of teacher and candidate to concentration of effort on those subjects required, at the expense—perhaps to the neglect—of others. In particular cases this may even seriously deform the school curriculum. This consideration must not be overlooked in formulating a normal list of requirements.

4. The tendency of all examinations is to stimulate preparatory study, the degree of such stimulation varying widely according to circumstances, and requiring, as in case of any other stimulus, very careful control. For such control the colleges must depend in the main on the schools; unless it is exercised, the results of the examination are of relatively slight value. Certain teachers and certain schools

are notoriously able to prepare candidates who can pass entrance examinations, but do little afterwards.

5. The entrance examination at its best is a healthful stimulus especially to an indolent candidate; it presents to the schools an external, independent, concrete standard by which their work may be measured to the satisfaction of the ambitious and successful, to the confusion of the unworthy; it enforces upon school committees the need of strengthening weak points.

6. On the other hand, besides the danger noted under 4, the examination has certain serious defects as a test. Examiner and teacher are separated by a wall with more or less numerous loopholes, catalogue specifications, former examinations, etc. Too often the examiner's object is merely to select the best of these loopholes, that is to "coach"—not to educate—his candidate.

It is difficult to proportion the parts of an examination in accordance with the relative importance of the corresponding topics. It is difficult even to make the questions so clear that some applicants shall not totally misunderstand them.

It is difficult to judge applicants fairly—in some cases even to mark their examinations justly—without personal acquaintance. Some always do themselves more than justice, others less.

Last and most important, while an entrance examination may be an adequate and accurate test of an applicant's knowledge of particular subjects, it is an indirect criterion of general mental capacity on the one hand, and of specific aptitude for the kind of work in view on the other.

7. In consideration of these defects of the entrance examination system, many colleges substitute admission by certificate; many others attempt to strengthen their weak points by a combination of the two systems.

Some of the advantages of a good certificate system are these:

(*a*) It requires supervision and examination of the work of the school by the college or by some other central body, thus showing strength or weakness in the work directly.

(*b*) It gives the certificated school authoritative recognition which, if deserved, it ought to have.

(*c*) It keeps school and college in touch with each other.

(*d*) It substitutes for the information test of examinations the judgment of a teacher to whom the applicant is personally known. A good teacher must generally be a better judge of mental capacity and aptitude than the best examiner.

Familiar difficulties of the certificate system are:

(*a*) The difficulty of establishing and maintaining—by law, or by college cooperation—the necessary "supervision and examination" of school work.

(*b*) The extreme diversity of work in different parts of the country and State. The certificate system should tend to remedy this.

(*c*) The reluctance of college officers to deny or suspend the acceptance of certificates from poor schools.

(*d*) The reluctance of school officers to deny certification to unfit applicants.

8. The tendency of present diversity is to localize education unduly. It is generally difficult for a candidate to prepare for a college in some other, perhaps distant State, as easily as for one in his own.

CONCLUSIONS AND RECOMMENDATIONS.

1. *Uniformity of requirements.*—The committee regards absolute uniformity of requirements as entirely inconsistent with the diversity of educational conditions in different States, and as not in itself desirable. Each community, large or small, must work upward as it best can toward its own ideal. Variation is the basis of evolution.

Needless arbitrary deviations from uniformity in mere details are vexatious and harmful to all concerned and should be removed as soon as possible by cooperation between colleges and schools.

To secure such degree of uniformity as is practicable, the committee recommends the approval by this society of a definite list of entrance requirements somewhat as follows:

Mathematics.—Arithmetic (complete); algebra, elementary; algebra, through quadratics; algebra, advanced; geometry, plane; geometry, solid; trigonometry, plane.

Science.—Physical geography, botany, chemistry, physics.

Language.—English, French, German, Latin.

General.—Free-hand drawing, United States history, some second subject in history.

This list includes the requirements of nearly all of the colleges. From this list are excluded the scattering odds and ends, writing, reading, partial arithmetic, mensuration, elementary mechanics, higher mathematics, civil government, local government, bookkeeping, elocution, mental science, logic, economics, theory of teaching, Miln's Realm of Nature, zoology, astronomy, geology, mineralogy, meteorology, natural history, biology, introduction to science, etymology, Latin elements of English, Spanish, and Greek. This diversity has crept in to some extent, no doubt, through the attempt on the part of colleges to meet the varying courses of their contributory schools through a system of options in requirements, and possibly to make the scientific courses level up to the classical ones without the necessity of imposing the dead languages on the student. But the effect has been to scatter and to produce confusion on the one hand, and to limit each college to its own field of cultivated schools on the other.

What some of these subjects are doing as requirements for engineering courses, unless as temporary makeshifts, is not easily comprehended. There is enough within the above list, that so many colleges agree upon, to fully occupy the time of any boy in his four years in the high school, and there is variety enough to give breadth of training. There is work in the five chief lines of mathematics, language and literature, history, science, and art. Any school course, on the one hand, and any college set of requirements, on the other, ought to include all of these lines.

Again, while the colleges should confine themselves to the above subjects, there is nothing in the list that does not properly fit into the school curriculum. Laboratory work of the right kind in physics, chemistry, and botany may be found in comparatively few schools, but it ought to be given in all high schools with four-year courses for their own sakes, irrespective of the demands of scientific colleges.

Somewhat apart from the other subjects named, stands manual training, including shop work and mechanical drawing.

It is obviously impossible, even if desirable, to make either of these a requirement for admission to engineering colleges generally. On the other hand, the engineering colleges should be the first to recognize the true value of hand and eye work as a form of education. The committee believes that, so far as practicable, such recognition should be more generally shown by the acceptance of certified work in manual training as an optional requirement by institutions accepting any optional subjects. As previously stated there are only two engineering colleges that at present require manual training.

2. *What should be required.*—It is difficult to generalize, to the extent of laying down absolute requirements to which all colleges should conform. Yet, broadly speaking, there exist to-day two grades of engineering colleges whose work lies about one year apart. For the first of these the minimum requirements should include the following subjects: Algebra (advanced), plane and solid geometry, physics with laboratory work, chemistry with laboratory work, New England requirements in English, two years of foreign language, American history and some additional history, free-hand drawing.

For the second grade the minimum requirements should include: Algebra

through quadratics, plane geometry, physics,[1] English along the line of New England requirements but less in amount, one year of foreign language, American history, free-hand drawing.

Below these are colleges, like some of the colleges of architecture and mechanic arts, that are forced by the necessities of environment or the terms of their foundation to maintain low standards of admission and do in course what other colleges throw into requirements. These should insist on requiring as a minimum: Arithmetic (complete), elementary algebra, plane geometry, English along the line of New England requirements, but less in amount, American history.

Any lower requirements than these bring students into college before they have completed their courses in the lower schools. This works a double injustice, through lessening the force and prestige of the preparatory school and making it necessary for the college to do some of its work.

The differentiation here spoken of is not confined to the requirements, but is naturally apparent in the courses. These gradations in colleges are inevitable. They constitute one of the expressions of the varying conditions of life in the different communities and sections of this broad land. The sooner that this is frankly and freely admitted and acted upon, the better for American education. The older and higher grade colleges should recognize the value and dignity of the work of those that are newer or of lower grade, and on the basis of quality rather than grade.

On the other hand, the newer or lower grade colleges ought to recognize that the graduates of the colleges of higher grade are more evenly educated, more broadly cultured and better equipped for professional life than their own, and cease trying to bring about an apparent equality of grade. President S. P. McCrea, of the New Mexico College of Agriculture and Mechanic Arts, writes: "New Western colleges like this will be more concerned in securing advanced standing for their engineering students in the older and high-grade institutions, than in attempting to put their work on the same plane without respect to conditions. Can your committee do anything in this direction? If not, can a committee be appointed to deal with this matter?" The same spirit is manifested by correspondents from some other points.

8. *Admission by certificate.*—In the opinion of the committee, the advantages of the certificate system as already outlined, are fundamental, and its defects are to a great extent temporary and remediable with the general "leveling up" of secondary school work. Here absolute uniformity is not to be thought of. The more general observance of the following principles is of the highest importance:

(*a*) As the primary essential, personal visitation and inspection, on the part of the college, of the school asking a commission.

(*b*) This commission to be limited as to time and reissued only after reinspection, or on full knowledge of the condition of the school.

(*c*) The reservation of the right of the college to withdraw the commission for cause shown.

(*d*) Certificates to show in detail the extent of the ground covered and actual time spent in each subject and to contain the personal recommendation of the superintendent or principal.

(*e*) Students received on certificate to be required to make up any deficiency in preparation that may appear in any certificated subject.

(*f*) The college to cultivate friendly relations with its accredited schools and to make clear, through publications and conferences, just what its requirements are.

In the application of these principles each college would necessarily work out its own details, and under present conditions be obliged to do its own visiting and inspecting. But there is no reason why the colleges should not cooperate in this matter under suitable restrictions, the commissioning of a school by one, involving its acceptance by others.

[1] In the opinion of the committee the physics should include laboratory work.

CHAPTER XIX.

EARLY HISTORY OF THE KINDERGARTEN IN ST. LOUIS, MO.[1]

INDUSTRIAL EDUCATION—WHERE IT SHOULD BEGIN.

There has been for some time a popular clamor in favor of the introduction of the arts and trades into public schools. It has been supposed by self-styled "practical" writers upon education that the school should fit the youth for the practice of some vocation or calling. They would have the child learn a trade as well as reading, writing, and arithmetic; and the most zealous of them demand that it shall be a trade, and not much else. But the good sense of the educational world, as a whole, has not been moved to depart from the even tenor of its way, and has defended its preference for technical, conventional, and disciplinary training of a general character, useful for each and every one, no matter what his vocation shall be. Who can tell, on seeing the child, what special vocation he will best follow when he grows up? Besides this, the whole time of the child, so far as it can be had without overtasking him, is needed from the period of 6 or 7 years to 16 years in order to give him a proper amount of this training in technical, conventional, and disciplinary studies. Moreover, it is evident that these general studies are the keys to the world of nature and man, and that they transcend in value any special forms of skill, such as arts and trades, by as great a degree as the general law surpasses the particular instance. It is to be claimed that arithmetic, the science of numbers, for example, is indispensable in a thousand arts and sciences, while each art has much in it that is special and of limited application in the other arts.

But, on the other hand, analytical investigation has done much in the way of singling out from the physical movement involved in the trades those which are common and may be provided for by general disciplines of the body, which may be introduced into the school along with the science underlying the art. For example, the theory and practice of drawing involves arithmetic and geometry, and also the training of the hand and eye. Thus, drawing furnishes a kind of propædeutics to all of the arts and trades, and could not fail to make more skillful the workman, whatever his calling. Drawing, then, may properly enter the programme of all schools, having its claim acknowledged to be a general discipline.

FROEBEL'S "GIFTS"—THEIR RATIONALE.

But while we may acknowledge the transcendent importance of the regular branches for the period of time claimed by the school at present—namely, from the age of 6 to 16—it must be conceded that the age from 4 years to 6 years is not mature enough to receive profit from the studies of the school. The conventional and the disciplinary studies are too much for the powers of the child of 4 years or 5 years. But the child of 4 years or 5 years is in a period of transition out of the

[1] From the St. Louis Annual Report for 1878–79.

stage of education which we have named "nurture." He begins to learn of the outdoor life, of the occupations and ways of people beyond the family circle, and to long for a further acquaintance with them. He begins to demand society with others of his own age outside his family, and to repeat for himself, in miniature, the picture of the great world of civil society, mimicking it in his plays and games. Through play the child gains individuality; his internal—"subjective," as it is called—nature becomes active, and he learns to know his own tendencies and proclivities. Through caprice and arbitrariness, the child learns to have a will of his own and not to exercise a mere mechanical compliance with the will of his elders.

It is at this period of transition from the life in the family to that of the school that the kindergarten furnishes what is most desirable, and in doing so solves many problems hitherto found difficult of solution. The genius of Frœbel has provided a system of discipline and instruction which is wonderfully adapted to this stage of the child's growth, when he needs the gentleness of nurture and the rational order of the school in due admixture. The "gifts and occupations," as he calls them, furnish an initiation into the arts and sciences; and they do this in a manner half playful, half serious.

Of the twenty gifts which the kindergarten system offers, the first six form a group having the one object to familiarize the child with the elementary notions of geometry. He learns the forms of solids, the cube, sphere, and cylinder, and their various surfaces; also, divisions of the cube and combinations of the cube and its divisions in building various objects. He learns counting and measuring by the eye, for the cube and its divisions are made on a scale of an inch and fractions of an inch, and the squares into which the surface of his table is divided are square inches. Counting, adding, subtracting, and dividing the parts of the cube give him the elementary operations of arithmetic, so far as small numbers are concerned, and give him a very practical knowledge of them; for he can use his knowledge, and he has developed it, step by step, with his own activity.

It is always the desideratum in education to secure the maximum of self-activity in the pupil. The kindergarten gifts are the best instrumentalities ever devised for the purpose of educating young children through self-activity. Other devices may do this—other devices have done it—but Frœbel's apparatus is most successful. It is this fact that occasions the exaggerated estimate which his disciples place upon the originality of Frœbel's methods. Long before his day it was known and stated as the first principle of pedagogy that the pupil is educated, not by what others do for him, but by what he is led to do for himself. But Frœbel's system of gifts is so far in advance of the other systems of apparatus for primary instruction as to create an impression in the mind of the one who first studies it that Frœbel is the original discoverer of the pedagogical law of self-activity in the pupil. The teacher who has already learned correct methods of instruction, or who has read some in the history of pedagogy, knows this principle of self-activity, but has never found, outside of the kindergarten, so wonderful a system of devices for the proper education of the child of 5 years old.

The first group of gifts, including the first six of the twenty, as already remarked, takes up the forms of solids and their division, and therefore deals with forms and number of solids. The second group of gifts includes the four from the seventh to the tenth, and concerns surfaces, and leads up from the manipulation of thin blocks or tablets to drawing with a pencil on paper ruled in squares. In drawing, the child has reached the ideal representation of solids by means of light and shade—marks made on a surface to represent outlines. The intermediate gifts—the eighth and ninth—relate to stick-laying and ring-laying, representing outlines of objects by means of straight and curved sticks or wires. This, in itself, is a well-devised link between the quadrangular and triangular tablets (which are

treated only as surfaces) and the art of drawing. We have a complete transition from the tangible solid to the ideal representation of it.

Counting and the elementary operations in numbers continue through all the subsequent groups of gifts, but in the first group are the chief object. In the first group the solid, in its various shapes, is the object of study for the child. He learns to recognize and name the surfaces, corners, angles, etc., which bound it. In the second group the surface and its corners or angles become the sole object. But the child begins the second group with the surface represented by tablets, thin blocks, and proceeds to represent mere outlines by means of sticks or wire (in the eighth gift), and then to leave the solid form altogether and to make an ideal one by means of pencil marks on slate or paper (in the tenth gift). The slate or paper, ruled in squares of an inch, like the kindergarten tables, is the best device for training the muscles of the fingers and hand to accuracy. The untrained muscles of the hand of the child can not guide the pencil so as to make entire forms at first; but by the device of the ruled squares he is enabled to construct forms by the simple process of drawing straight lines, vertical, horizontal, and oblique, connecting the sides and corners of the ruled squares. The training of the eye and hand in the use of this tenth gift is the surest and most effective discipline ever invented for the purpose.

Here it becomes evident that if the school is to prepare especially for the arts and trades it is the kindergarten which is to accomplish the object, for the training of the muscles, if it is to be a training for special skill in manipulation, must be begun in early youth. As age advances, it becomes more difficult to acquire new phases of manual dexterity.

Two weeks' practice of holding objects in his right hand will make the infant, in his first year, right-handed for life. The muscles, yet in a pulpy consistency, are very easily set in any fixed direction. The child trained for one year on Frœbel's gifts and occupations will acquire a skillful use of his hands and a habit of accurate measurement of the eye which will be his possession for life.

But the arts and trades are provided for in a still more effective manner by the subsequent gifts. The first group, as we have seen, trains the eye and the sense of touch, and gives a technical acquaintance with solids and with the elementary operations of arithmetic. The second group frees him from the hard limits which have confined him to the reproduction of forms by mere solids, and enables him to represent by means of light and shade. His activity at each step becomes more purely creative as regards the production of forms and more rational as regards intellectual comprehension, for he ascends from concrete, particular, tangible objects to abstract general truths and archetypal forms.

The third group of gifts includes the eleventh and twelfth, and develops new forms of skill, less general and more practical. Having learned how to draw outlines of objects by the first ten gifts, the eleventh and twelfth gifts teach the pupil how to embroider; i. e., how to represent outlines of objects by means of needle and thread. The eleventh gift takes the first step, by teaching the use of the perforating needle. The child learns to represent outlines of forms by perforations in paper or cardboard. Then, in the twelfth gift, he learns the art of embroidering, and, of course, with this he learns the art of sewing and its manifold kindred arts. The art of embroidery calls into activity the muscles of the hand, and especially those of the fingers, the eye in accurate measurement, and the intellectual activities required in the geometrical and arithmetical processes involved in the work.

The fourth group of gifts (including the thirteenth to the eighteenth) introduces the important art of weaving and plaiting.

Among the primitive arts of man this was the most useful. It secures the maximum of lightness with the maximum of strength, by using fragile material

in such a manner as to convert the linear into the surface and combine the weak materials into the form of mutual firm support.

The thirteenth gift (with which the fourth group begins) teaches how to cut the paper into strips; the fourteenth weaves the strips into mats or baskets, with figures of various devices formed by the meshes; the fifteenth gift uses thin slats of wood for plaiting, and the sixteenth uses the same, jointed, with a view to reproducing forms of surfaces; the seventeenth gift intertwines paper, and the eighteenth constructs elaborate shapes by folding paper. This group constructs surfaces by the methods of combining strips or linear material. Vessels of capacity (baskets, sieves, nets, etc.), clothing (of woven cloth), and shelter (tents, etc.) are furnished by branches of this art.

Wood is linear in its structure, and stronger in the direction of the grain of the wood. Hence it became necessary to invent a mode of adding lateral strength by crossing the fibers, in the form of weaving or plaiting, in order to secure the maximum of strength with the minimum of bulk and weight. Besides wood, there are various forms of flexible plants (the willow, etc.) and textile fibers (hemp, flax, cotton, etc.) which can not be utilized except in this manner, having longitudinal but not lateral cohesion.

In the fourth group of gifts the industrial direction of the work of the kindergarten becomes the most pronounced. There is more of practical value and less of theoretic value in its series of six gifts (thirteenth to eighteenth). But its disciplines are still general ones, like drawing, and furnish a necessary training for the hands and eyes of all who will labor for a livelihood; and, besides these, for all who will practice elegant employments for relaxation (ladies' embroidery), or athletic sports and amusements (the games and amusements that test accuracy of hand and eye, or mathematical combination, marksmanship, hunting, fishing, ball playing, archery, quoits, bowling, chess playing, etc.).

The fifth group, including the nineteenth and twentieth gifts, teaches the production of solid forms, as the fourth teaches the production of surfaces from the linear. The nineteenth, using corks (or peas soaked in water) and pieces of wire or sticks of various lengths and pointed ends, imitates various real objects and geometrical solids by producing their outlines, edges, or sections. This gift, too, furnishes the preparation for drawing in perspective. The twentieth and last gift uses some modeling material (potter's clay, beeswax, or other plastic substance), and teaches modeling of solid objects. This group of gifts is propædeutic to the greater part of the culinary arts, so far as they give shape to articles of food. It also prepares for the various arts of the foundry—casting or modeling—of the pottery, etc., and the fine arts of sculpture and the preparation of architectural ornament.

In the common school, drawing, which has obtained only a recent and precarious foothold in our course of study, is the only branch which is intended to cultivate skill in the hand and accuracy in the eye. The kindergarten, on the other hand, develops this by all of its groups of gifts.

Not only is this training of great importance by reason of the fact that most children must depend largely upon manual skill for their future livelihood, but, from a broader point of view, we must value skill as the great potence which is emancipating the human race from drudgery by the aid of machinery. Inventions will free man from thralldom to time and space.

By reason of the fact, already adverted to, that a short training of certain muscles of the infant will be followed by the continued growth of the same muscles through his after life, it is clear how it is that the two years of the child's life (his fifth and sixth), or even one year, or a half year, in the kindergarten will start into development activities of muscle and brain which will secure deftness and delicacy of industrial power in all after life. The rationale of this is found in the fact that it is a pleasure to use muscles already inured to use; in fact, a

much-used muscle demands a daily exercise as much as the stomach demands food. But an unused muscle, or the mere rudiment of a muscle that has never been used, gives pain on its first exercise. Its contraction is accompanied with laceration of tissue, and followed by lameness, or by distress on using it again. Hence it happens that the body shrinks from employing an unused muscle, but, on the contrary, demands the frequent exercise of muscles already trained to use. Hence in a thousand ways, unconscious to ourselves, we manage to exercise daily whatever muscles we have already trained, and thus keep in practice physical aptitudes for skill in any direction.

The carriage of a man who appears awkward to us is so because of the fact that he uses only a few muscles of his body, and holds the others under constraint, as though he possessed no power to use them. Freedom of body, which we term gracefulness, is manifested in the complete command of every limb by the will. This is the element of beauty in the Greek statuary. The gymnastic training may be easily recognized in a young man by his free carriage. As he moves he uses a greater variety of muscles than the man of uncultivated physique. It follows that a muscle once trained to activity keeps itself in training, or even adds by degrees to its development, simply by demanding its daily exercise, and securing it by some additional movement which it has added as subsidiary to activities in which other muscles are chiefly concerned. In his manner of sitting or rising, of walking or running, even of breathing, of writing, or reading, one man varies from another through the use or disuse of subsidiary muscles, thus kept in training or allowed to remain as undeveloped rudiments.

I have, in this protracted discussion of the significance of Frœbel's gifts as a preparation for industrial life, indicated my own grounds for believing that the kindergarten is worthy of a place in the common-school system. It should be a sort of subprimary education, and receive the pupil at the age of 4 or 4½ years, and hold him until he completes his sixth year. By this means we gain the child for one or two years when he is good for nothing else but education, and not of much value even for the education of the school as it is and has been. The disciplines of reading and writing, geography and arithmetic, as taught in the ordinary primary school, are beyond the powers of the average child not yet entered upon his seventh year. And beyond the seventh year the time of the child is too valuable to use it for other than general disciplines—reading, writing, arithmetic, etc., and drawing. He must not take up his school time with learning a handicraft.

The kindergarten utilizes a period of the child's life for preparation for the arts and trades, without robbing the school of a portion of its needed time.

Besides the industrial phase of the subject, which is pertinent here, we may take note of another one that bears indirectly on the side of productive industry, but has a much wider bearing. At the age of 3 years the child begins to emerge from the circumscribed life of the family, and to acquire an interest in the life of society, and a proclivity to form relationship with it. This increases until the school period begins, at his seventh year. The fourth, fifth, and sixth years are years of transition, not well provided for either by family life or by social life in the United States. In families of great poverty, the child forms evil associations on the street, and is initiated into crime. By the time he is ready to enter the school he is hardened in vicious habits, beyond the power of the school to eradicate. In families of wealth, the custom is to intrust the care of the child in this period of his life to some servant without pedagogical skill, and generally without strength of will power. The child of wealthy parents usually inherits the superior directive power of the parents, who have by their energy acquired and preserved the wealth. Its manifestation in the child is not reasonable, considerate will power, but arbitrariness and self-will—with such a degree of stubbornness that it quite overcomes the much feebler native will of the servant who has charge of the children. It is difficult to tell which class (poor or rich) the kindergarten

benefits most. Society is benefited by the substitution of a rational training of the child's will during his transition period. If he is a child of poverty, he is saved by the good associations and the industrial and intellectual training that he gets. If he is a child of wealth, he is saved by the kindergarten from ruin through self-indulgence and the corruption ensuing on weak management in the family. The worst elements in the community are the corrupted and ruined men who were once youth of unusual directive power—children of parents of strong wills.

The kindergarten will give the physical aptitude for manual skill. After the common-school education is finished, the "manual-training school" will complete the preparation for a trade. In the "school shops," as the manual-training schools are sometimes called, the pupil learns how to use the various tools which belong to most of the industries—the ax, saw, plane, auger, hammer, square, chisel, and file. There are very many tools, but they are for the most part only applications of these few instruments.

Cost of Tuition in the Kindergarten.

The total amount of salaries in this department for the 131 paid teachers was $21,860; average number of pupils belonging in the kindergartens was 3,841, making the average cost per pupil $5.70; cost for each of the 6,202 pupils enrolled, $3.52.

The salaries paid have been much reduced.

	First year.	Second year.	Third year.	Fourth year.	Fifth year.
For whole day, director	$450.00	$475.00	$500.00	$550.00	$600.00
For half day, director	250.00	275.00	300.00	325.00	350.00
For whole day, paid assistant	200.00	.....	.....	.....	.....
For half day, paid assistant	125.00	.....	.....	.....	.....

The cost of tuition in the kindergarten for 1875–76 was, for each pupil belonging, $11.36; for each pupil enrolled, $5.76. For 1876–77, for each pupil belonging, $9; for each pupil enrolled, $4.05.

This shows a constant reduction in the cost of instruction in the kindergarten, and forms a very important consideration in the question of the introduction or continuance of the kindergarten in the public-school system.

The average cost of tuition in all the schools is $16.73 for each pupil belonging, and $11.78 for each pupil enrolled in the course of the year.

In my report for 1875–76 I have discussed the several questions relative to the course of study and management of the kindergarten, and in my report for 1876–77 I have given extended statistics as to results.

As the kindergarten has now been in operation for six years, and on a very extended scale, the time has arrived when the subject may be discussed in the light of experience, and satisfactory conclusions reached as to the advisability of continuing and extending the system thus far developed.

The history of the establishment of the kindergarten with us is perhaps of sufficient interest to be rehearsed here.

1. From the report of the superintendent for 1870–71:

The average duration of the school life of a child in manufacturing districts is only three entire years. Commencing at the age of 7, he completes his school education at 10. If he could be properly cared for in school at 5 years of age his school life would last five years. This period would suffice to make a durable impression on his life.

The exclusion of pupils under 7 years of age, to which I have alluded in previous reports, still continues, but not to such an extent as formerly. In certain sections of the city where the influences are corrupting to the children, they being obliged

to play on the street, it is decidedly better to have them in school at an early age, and to so far modify the tasks imposed on them as to prevent overstraining their delicate organisms. The kindergarten system of culture for the young is justly receiving much attention from educators everywhere. To it we must look for valuable hints on the method of conducting our instruction in the lowest primary grades.

The establishment of an experimental kindergarten was accordingly recommended. It got no further, however, than the experiment made at the Everett Primary School, wherein some of the features of the kindergarten were adopted.

2. Colonel Rombauer introduced a resolution, in November, 1871, into the board, appointing a committee for a report on "play schools."

This committee reported March 12, 1872, as follows (the report being laid over):

REPORT OF COMMITTEE ON PLAY SCHOOLS.

To the President and Board of Directors of St. Louis Public Schools:

An investigation into the merits of play schools, their practical operation in other places, and the earnest enthusiasm of all supporters of their institution, has convinced your committee that our public-school system can no doubt be improved in that direction. However, though highly recommended, the play school has nowhere found a general application. An institution of this description, under the direction of Prof. A. Douai, of Newark, N. J., is the only one which enjoys the direct support of the public-school authorities. This play school is in a flourishing condition, and the subsequent success of its pupils in the district schools is stated to be most satisfactory, as these pupils are almost invariably at the head of their classes.

While a great many children do not enjoy the advantages of the supervision and guidance of parents whose intellectual culture, pecuniary means, and business relations would permit to give the necessary time, or to secure playgrounds, playmates, and playthings which would invite the full bodily and mental activity of the child, institutions which, by association and combination of means, can secure these desired facilities must be highly commendable.

From the reviewed and digested experience of others, your committee has come to the conclusion that an educational institution preceding the day education of the district schools, dealing with children at the tender age when they are most susceptible for lasting impressions, should try to attain, besides its negative benefits, the following positive objects:

1. To develop the individuality of the child sufficiently that the same should not be obliterated by subsequent class education.
2. To shape its character, and train it to perseverance, strength, and mental vigor.
3. To elicit talents, independent action, and leading tendencies of mind, by giving them the opportunity of, and by inviting, their expression.
4. To acquaint the child with nature and its forces through play.
5. To lead the child to habits of order, classification, and system.
6. To give the child a taste for beauty as the best safeguard against vice.
7. To give the child ample exercise and the surroundings of health.

The above objects can be advanced to no inconsiderable extent by the institution of play schools, and this influence will aid our district-school system beyond expectation. However, no definite method in their administrations and no definite system in their organization has yet been arrived at. For this reason a practical test of the system in our own midst, and under the supervision of the board and its officers, would appear to be most desirable. It should be also ascertained whether there is an actual demand for an institution of that kind in our community.

In one sense the whole of life is an education, for man is a being that constantly develops—for good or evil. In every epoch of his life an education goes on. There are well-defined epochs of growth or of education; that of infancy, in which education is chiefly that of use and want, the formation of habits as regards the care of the person, and the conduct within family life; that of youth, wherein the child learns in the school how to handle those instrumentalities which enable him to participate in the intellectual or theoretical acquisitions of the human race, and wherein, at the same time, he learns those habits of industry, regularity and punctuality, and self-control, which enable him to combine with his fellow-men

in civil society and in the State; then there is that education which follows the period of school education—the education which one gets by the apprenticeship to a vocation or calling in life. Other spheres of education are the State, or body politic, and its relation to the individual, wherein the latter acts as a citizen, making laws through his elected representatives, and assisting in their execution; the church, wherein he learns to see all things under the form of eternity, and to derive thence the ultimate standards of his theory and practice in life.

Before Miss Blow's experiment in the Des Peres School the kindergarten was only a vague dream in the St. Louis schools. Since that time the following has been the progress:

Year.	Number of kindergartens.			Number of teachers.			Number of pupils enrolled.			Average number belonging.
	Forenoon.	Afternoon.	Total.	Paid.	Unpaid.	Total.	Boys.	Girls.	Total.	
1873-74	1	-------	1	1	3	4	30	38	68	42
1874-75	3	1	4	4	13	17	130	141	271	138
1875-76	7	5	12	12	38	50	533	508	1,041	528
1876-77	16	14	30	32	150	182	1,506	1,827	3,333	1,502
1877-78	22	18	40	60	139	199	2,407	2,952	5,359	1,469
1878-79	27	26	53	131	65	196	3,845	3,357	6,202	3,843

CLAIM OF THE KINDERGARTEN FOR A PLACE IN THE PUBLIC-SCHOOL SYSTEM.

The question of the kindergarten can not be settled without considering many subordinate questions.

Your committee therefore recommend to aid such an institution with means, provided citizens taking an interest in similar educational institutions will give a practical expression to such interest by also aiding the same with their private means.

Your committee therefore recommend the adoption of the following resolutions:

1. That $1,000 are hereby appropriated for the institution of a play school, provided private citizens furnish a similar amount for the same purpose.
2. That the institution and the funds created as above shall be under the control of the president, superintendent, and chairman of the teachers' committee of the board.
3. That the objects of that school shall be the same as expressed in this report.
4. That admission to said play school shall be free.
5. That the citizens contributing to the establishment of that play school may select its locality, and elect an advisory committee for its management.
6. That the superintendent of the public schools shall report from time to time upon its condition and progress.

ROBT. J. ROMBAUER.
W. DŒNCH.
THOMAS RICHESON.

3. From superintendent's report for 1871-72:

From his third year, the child begins to widen the sphere of his activity so much as to extend it beyond the family influence. Through play he comes in contact with children of other families; and soon after this commences he needs the counterbalancing influences of the school. Through contact with other children in play—especially where, as happens in cities, the street is the place of this association—his will develops powerfully, and something more is needed for its control than the mere family nurture.

The régime of the school (more general than that of the family) is needed to prevent arbitrariness and caprice, and to secure the growth of proper respect for elders, and for moral and civil ordinances. That threefold reverence which Goethe speaks of as the basis of all higher life—reverence for superiors, for equals, and for inferiors—is very difficult to inculcate if the child remains too long under family influence, without the training of the school. School discipline is found to be far more potent when applied at the age of 5 than at the age of 8 years.

I hope another year will witness the formation of a sufficient number of small

primary schools—founded more or less on the kindergarten plan—to accommodate all of the localities situated near the river and in our manufacturing districts. A genuine kindergarten, as an experiment, would furnish additional hints to our teachers and suggestions to the board, enough to doubly repay the cost of its support.

4. From superintendent's report for 1872-73:

We do not look so much to the gain in intellectual possessions as to the training of the will into correct habits during the years previous to the seventh. After his third year the child becomes social, and hungers for companionship. In the school he can secure this with less danger to him than on the street. Such careful training in habits of regularity, punctuality, industry, cleanliness, self-control, and politeness as are given in the ordinary primary school and still more efficiently in the well-conducted kindergarten, are of priceless benefit to the community. They lessen the number of rough, ungovernable youths, whose excesses are the menace of the peace of society.

The offer of Miss Susie E. Blow to undertake gratuitously the instruction of one teacher appointed by the board, and to supervise and manage a kindergarten, provided the board would furnish the rooms and a salaried teacher, was accepted; and in the report of the teachers' committee, August 26, 1873, it was recommended—

That room No. 4 of the Des Peres School be devoted for the present year to the purpose of ascertaining, by a faithful experiment, what valuable features the kindergarten may have that can be utilized in our primary schools; and, for this purpose, that Miss Mary A. Timberlake be assigned to this room, with rank of first assistant; and that Miss Susie E. Blow, having proffered her services gratuitously, the same be accepted, and the school be placed under her control and supervision.

Teachers' Committee.

The question of the kindergarten also involves, besides this one of province—i. e., the question whether there is a place for it—the consideration of its disciplines, or what it accomplishes in the way of theoretical insight or of practical will power; these two, and the development of the emotional nature of the human being. Exactly what does the kindergarten attempt to do in these directions? And then, after the what it does is ascertained, arises the question whether it is desirable to attempt such instruction in the school; whether it does not take the place of more desirable training, which the school has all along been furnishing; or whether it does not, on the other hand, trench on the province of the education within the family, a period of nature wherein the pupil gets most of his internal or subjective emotional life developed? If the kindergarten takes the child too soon from the family and abridges the period of nature, it must perforce injure his character on the whole; for the period of nurture is like the root life of the plant, essential for the development of the above-ground life of the plant, essential for the public life of the man, the life wherein he combines with his fellow-men.

Then, again, there is involved the question of education for vocation in life—the preparation for the arts and trades that are to follow school life—as the third epoch in life education. Should the education into the technicalities of vocations be carried down into the school life of the pupil; still more, should it be carried down into the earliest period of transition from the nurture period to the school period?

Besides these essential questions, there are many others of a subsidiary nature—those relating to expense, to the training of teachers and their supply, to the ability of public-school boards to manage such institutions, to the proper buildings

for their use, the proper length of sessions, the degree of strictness of discipline to be preserved, etc. The former essential questions relate to the desirability of kindergarten education; the latter relate to the practicability of securing it.

The most enthusiastic advocates of the kindergarten offer, as grounds for its establishment, such claims for its efficiency as might reasonably be claimed only for the totality of human education, in its five-fold aspect—of nurture, school vocation, State, and church. If what they claim for it were met with as actual results, we certainly should realize the fairest ideals of a perfected type of humanity at once. Such claims, however, can be made only of a lifelong education in its five-fold aspect, and not of any possible education which lasts only from one to four years in the life of the individual. Notwithstanding this exaggeration, it may prove to be the case that the kindergarten is justified in claiming a province heretofore unoccupied by the school or by family nurture, and a province which is of the utmost importance to the right development of those phases of life which follow it. It is, indeed, no reproach to the friends of the "new education" (as they call it) to accuse them of exaggeration. The only fault which we may charge them with is a tendency to ignore or underrate the educational possibilities of the other provinces of human life, and especially those of the school as it has hitherto existed.[1]

---

[1] To illustrate the breadth of view which the advocates of the kindergarten entertain in regard to the theory and practical value of the kindergarten, I quote here a statement of its rationale furnished me by Miss Elizabeth Peabody, justly considered the leading advocate for the new education in this country:

"The rationale of Froebel's method of education is only to be given by a statement of the eternal laws which organize human nature on the one side and the material universe on the other.

"Human nature and the material universe are related contrasts, which it is the personal life of every human being to unify. Material nature is the unconscious manifestation of God, and includes the human body, with which man finds himself in relation so vital that he takes part in perfecting it by means of the organs; and this part of nature is the only part of nature which can be said to be dominated vitally by man, who, in the instance of Jesus Christ, so purified it by never violating any law of human nature—which (human nature) is God's intentional revelation of Himself to each—that He seems to have had complete dominion, and could make Himself visible or invisible at will; transfiguring His natural body by His spiritual body, as on the Mount of Transfiguration; or consuming it utterly, as on the Mount of Ascension. Whether man, in this atmosphere, will ever do this, and thus abolish natural death, or not, there is no doubt there will be infinite approximation to this glorification of humanity in proportion as education does justice to the children, as Froebel's education aims to do it; for it is his principle to lead children to educate themselves from the beginning—like Socrates's demon—forbidding the wrong and leaving the self-activity free to goodness and truth, which it is destined to pursue forever and ever."

A writer in the Canadian School Journal gives utterance to the following estimate of the value of kindergartens:

"Graduated from a true kindergarten, a child rejoices in an individual self-poise and power which makes his own skill and judgment important factors of his future progress. He is not like every other child who has been in his class; he is himself. His own genius, whatever it may be, has had room for growth and encouragement to express itself. He therefore sees some object in his study, some purpose in his effort. Everything in his course has been illuminated by the same informing thought; and, therefore, with the attraction that must spring up in the young mind from the use of material objects in his work, instead of a weariness, his way has been marked at every step by a buoyant happiness and an eager interest. Any system that produces such results is educationally a good system. But when you add that all this has been done so naturally and so judiciously that the child has derived as much physical as mental advantage, and an equally wholesome moral development, who can deny that it is superior to any other yet devised or used, and that, as such, it is the inalienable birthright of every child to be given the advantages of its training? * * * Before the time of Froebel, the science of pedagogics was founded upon abstruse thought, although sometimes introducing—as in the various object systems—the concrete form as a means of education; but Froebel, by a Divine inspiration, laid aside his books, wherein theory mystified theory, and studied the child.

"He said, God will indicate to us in the native instincts of His creature the best method for its development and governance. He watched the child at its play and at its work. He saw that it was open to impressions from every direction; that its energies were manifested by unceasing

The disciples of Froebel everywhere see the world in this way. With them the theory of the kindergarten is the theory of the world of man and nature. Froebel himself was as much a religious (or moral) enthusiast as a pedagogical reformer. The moral regeneration of the race is the inspiring ideal which his followers aim to realize.

I do not disparage this lofty ideal; it is the ideal which every teacher should cherish. No other one is a worthy one for the teacher of youth! But I think that any gifted teacher in our district schools, our high schools, or our colleges may, as reasonably as the teacher of the kindergarten, have this lofty expectation of the moral regeneration of the race to follow from his teachings. If the child is more susceptible at the early age when he enters the kindergarten, and it is far easier then to mold his personal habits, his physical strength and skill, and his demeanor toward his equals and his superiors, yet, on the other hand, the high-school teacher or the college professor comes into relation with him when he has begun to demand for himself an explanation of the problem of life, and it is possible, for the first time, at this age to lead him to insight—the immediate philosophical view of the universality and necessity of principles.

Insight is the faculty of highest principles, and of course more important than all other theoretical disciplines. It is therefore probable that the opportunity of the teacher who instructs pupils at the age of 16 years and upward is, on an average, more precious for the welfare of the individual than that of the teacher whose pupils are under 6 years. This advantage, however, the teacher of the youngest pupils has, that she may give them an influence that will cause them to continue their education in after life. The primary school, with its four years' course, usually enrolls five pupils where the grammar school, with a course of four years, enrolls only one pupil. The importance of the primary school is seen in the fact that it affects a much larger proportion of the inhabitants of a community, while the importance of the high school rests on the fact that its education develops insight and directive power, so that its graduates do most of the thinking and planning that is done for the community.

But there are special disciplines which the child of 5 years may receive profitably that the youth of 16 would not find sufficiently productive. I have already discussed, under the topic of Evening Schools, the industrial training that the kindergarten furnishes. With the author's permission, I make the following extracts from an admirable (unpublished) lecture by Miss Susan E. Blow—to whom our kindergartens are so deeply indebted—on the subject of the several phases of the kindergarten education which form its distinctive features of contrast with other education:

THE EDUCATIONAL VALUE OF THE GIFTS AND OCCUPATIONS.

Let a child try to fashion his lump of clay into a bird's nest, and, though his effort yield no other result, it will certainly lead him to examine carefully the next bird's nest he sees. Let him make an apple and a pear, and he must feel their difference in form as he would never have done had he simply looked at the two

curiosity and unceasing restlessness; that, if left to itself, the impossibility of reaching any satisfactory conclusions in its researches little by little stifled its interest; the eager desire to explore deeply the world of ideas and objects before him passed into a superficial observation, heeding little and sure of nothing. He saw that the law which made it flit from object to object in this unceasing motion was a law of development implanted by God, and therefore good; but that, unless it were directed and given aim and purpose, it became an element of mischief as well. Then what could be done? How was the possible angel to be developed and the possible devil to be defeated? Froebel said: 'If we take God's own way, we must be right; so let us direct into a systematic but natural course of employment all these tender fancies, these fearless little hands and feet, and these precious little eager souls; and then we shall work with the divine love and intelligence and it with us, and our children shall find the good and avoid the evil.' Then year was added to year of thought and study and practice, until he gave his system to the world in its present completed form."

fruits. Let him attempt to lay with his sticks the outline of a house, and his attention can not fail to be caught by facts of direction and proportion. Let him apply numbers in weaving, and their relations grow interesting to him. Lead him to construct symmetrical figures, and he must feel the laws of symmetry. Teach him rhythmic movements, and he must recognize rhythm. All things are revealed in the doing, and productive activity both enlightens and develops the mind.

It has always been a difficult problem to strike the balance between knowledge and power. The mind is not a sponge, nor is education the absorption of facts. On the other hand, nothing is more dangerous than energy uncontrolled by knowledge and insight. The mind, like the stomach, suffers from overloading, yet both need constant food. The test of healthy assimilation is increasing strength, and we know we are supplying the mind with the right kind and amount of food if we notice a gain in vigor and originality. The child's intense play is nature's effort to order the thronging impressions of the first years of life, and the kindergarten simply follows nature in alternating receptive and creative activities and in constantly registering the results of perception in reproduction.

In an age so analytical and scientific as our own, the kindergarten has a special value. Scientific methods need to be supplemented in education by artistic processes. The scientist, beginning with the embodied fact, seeks its relations and its causes; the thought of the artist is the final cause of the statue, the painting, or the poem. The scientist, "handicapped by fact and riveted to matter," struggles painfully toward the spiritual, while before the artist the invisible is constantly shaping the visible and the eternal declaring itself in the transitory. The restless scientist strives to order a bewildering variety; the artist instinctively realizes the unity from which variety is evolved, and feels the soul of the whole animating each particular part. We prepare the children for spiritual insight when we lead them to create.

Again, the representative system is death to superficiality and self-conceit. The child's imperfect results teach him humility, and stir him to fresh effort. He is constantly testing his perceptions by production, and measuring himself by his attainment. He learns that what he can use is his; that only what he consciously holds he truly possesses. He finds out in what directions he can best work, and transforms uncomprehended tendency into definite character. He advances, on the one hand, from perception to conception, from conception to reproduction, from reproduction to definition; and, on the other, from an instinctive to a self-directing activity, and from this to self-knowledge and self-control. Thus, by the same process, he unlocks creation and realizes in himself the image of his Creator.

The order of the kindergarten gifts follows the order of mental evolution: and at each stage of the child's growth, Froebel presents him with his "objective counterpart." "The child," he says, "develops, like all things, according to laws as simple as they are imperative. Of these, the simplest and most imperative is: That force existing must exert itself; exerting itself, it grows strong; strengthening, it unfolds; unfolding, it represents and creates; representing and creating, it lifts itself to consciousness and culminates in insight." This perception of the course of development determines his idea of the stages of early education. It should aim, first, to strengthen the senses and muscles, conceived as the tools of the spirit; second, to prepare for work by technical training, and to aid self-expression by supplying objects which, through their indefiniteness, may be made widely representative; third, to provide material adapted to the conscious production of definite things, and diminish the suggestiveness of this material in direct ratio to the increase of creative power; and, fourth, by analysis of the objects produced, and the method of their production, lift the child to conscious communion with his own thought. The first stage of this educational process is realized through the songs for mother and child; the second, through the kindergarten games, the simpler occupations, and the first two gifts; the third, through the exercises with blocks, tablets, slats, sticks, and rings, and the work in drawing, folding, cutting, peas work, and modeling; and the fourth, through the wise appeal of the kindergartener to the thought of the child, as she leads him slowly from the what to the how, and from the how to the why and wherefore of his own action.

The definitely productive exercises begin with the third gift. Froebel contends that the proverbial destructiveness of children is a perversion of the faculties of investigation and construction, and that the broken toys strewn over our nursery floors express the mind's impatient protest against finished and complicated things. Unable to rest in externals, the child breaks his toys to find out "what is inside," and, scornful of what makes no appeal to his activity, he turns from the most elegant playthings to the crude results of his own manufacture. What he wants

is, not something made for him, but material to make something himself. What he needs is an object which he can take to pieces without destroying, and through which he can gratify his instinct to transform and to reconstruct.

At the same time, the possibilities of the object must not be too varied, and it must be suggestive through its limitations. The young mind may be as easily crushed by excess as it is paralyzed by defect. Hence Froebel's choice of a cube divided into eight smaller cubes. It is easily separated into its elements, and easily reconstructed. It is capable of a reasonable number of transformations, and its crude resemblances satisfy the child's crude thought. It offers no variety of form to confuse his mind, but rigidly confines him to vertical and horizontal, to the right angle and the square. Moreover, he can scarcely arrange his blocks in any way without their taking forms which will suggest some object he has seen. If he piles them one above the other, a word from mother or kindergartener enables him to see in the unsought result of his doings a tower, a light-house, or a lamp-post. If he arranges them side by side, he is confronted with a wall; if in two parallel rows, behold the railroad. The change of a single block transforms the railroad into a train of cars; and, with another movement, the cars vanish in a house. Having, as it were, reached these results accidentally, the child next directly aims to reproduce them; and thus, through the suggestiveness of his material, is helped from an instinctive to a self-directing activity, and from simple energy to definite production. This point once attained, he triumphs over more and more complicated material, and constrains an ever-increasing variety of elements to obey his thought. With planes and sticks he advances to surface representation, and prepares the way for drawing, and finally begins, of himself, to form letters and to spell out the names of familiar things.

His progress, like that of the race, moves thus from the concrete to the abstract, from the fact to the picture, and from the picture to the sign. Through analysis of their productions the children are slowly awakened to facts of form and relations of number, and led to the clear and precise use of language. As they grow older, the analysis becomes more definite and extended; and whereas the baby beginners only name the objects they produce, the more advanced children tell how they make each object, and the graduating class must be able to resolve whatever they create into its elements, and state the facts of form, number, direction, and relation which it illustrates. I consider this final stage very important, for the reason that it makes clear to the mind the meaning of all its experiences, and leads from the particular fact to the principle governing all the facts of the given class.

With children who have completed the pure kindergarten course the gifts may be profitably used to teach the rudiments of geometry and arithmetic. The geometric forms are first recognized, then sought under their veiled manifestations in nature, then applied in construction, then consciously produced, clearly analyzed, and sharply defined, and finally shown in their relations to each other. Thus the child who begins by simply calling his building blocks "cubes" will end by recognizing in his cube the solid, the polyhedron, the hexahedron, the prism, and the parallelopiped, and will comprehend its precise definition as a rectangular parallelopiped whose faces are equal squares. So, beginning by pointing out the square corners of his cube, he ends with the definite conception of a right angle, as produced when two straight lines meet each other so as to make the adjacent angles equal. All the simple problems of geometry may be illustrated to perception and grasped as matters of fact, and the mind thus be prepared for the geometrical reasoning of later years.

It is unnecessary to enlarge upon the evident adaptation of the gifts to the teaching of arithmetic. Infinitely varied exercises in counting and in the four fundamental rules may be given with sticks, while the divided solids offer striking illustrations of fractional parts. Halves, quarters, and eighths must grow clear through the right use of the third and fourth gifts, while the fifth and sixth lead on in their natural division to thirds, ninths, and twenty-sevenths, and may also be used to illustrate halves, quarters, sixths, and twelfths. The salient features of the method used are: (1) To excite interest in the relations of numbers, rather than to give mechanical drill; (2) to constantly associate number and form, making them mutually illustrative; (3) to apply numbers to mechanical and artistic production. Whereas, in the kindergarten proper, the child abstracted from his productions numerical facts, he now directly seeks in his constructions to solve numerical problems. To illustrate: With a given number of blocks the children are required to build a house of stated height, breadth, and thickness, with a fixed number of windows and doors of definite dimension, and, having built it, to calculate its square and cubic contents. With their tablets they make squares, oblongs, rhombs, etc., of different sizes, noting length, breadth, and con-

tents; or with their sticks develop symmetrical figures from different math
ical centers, calculating themselves the number of sticks required for eac
addition. Gradually they grow capable of abstract exercises, and, far fron
ing vexation in multiplication and madness in fractions, their lessons in arith
are to them a delight and an inspiration.

From this imperfect survey of the gifts let us turn now to the occupa
These are perforating, sewing, drawing, intertwining, weaving, folding, cu
peas work, cardboard and clay modeling.

The perforating tool is a sharp needle fastened into a wooden handle. H
this in a perfectly vertical position, the child pricks small round holes in
Little children are provided with drawings in bold lines, and by perforating
lines produce on the opposite side of the paper a raised outline of the draw
ure. As they grow more expert, they produce pictures in relief by delicatel
forating the surface between the lines. They also receive paper marked
squares, and, first pricking the corners of these squares, and then by carefu
forations connecting these corners, obtain vertical and horizontal lines of dif
lengths. These are next united to form figures, and as the eye gains accurac
the hand precision, advance is made to slanting and curved lines and their
binations.

Squared paper perforated only at the corners, and outline pictures perfo
at distances of about the eighth of an inch, give the basis of the sewing exe
Armed with worsted and an embroidery needle, the child connects the corn
the paper and works various combinations of lines, or carefully retraces th
lines of pictures. The salient feature in the new occupation is variety of
and through this simple work the harmonies and contrasts of color may be
cated and the attention directed to the colors of natural objects.

Sewing and pricking culminate in drawing, which again emphasizes both
binations of lines and representation of objects—hinting, on the one hand, tl
ments of design and on the other the first principles of artistic reprodu
Beginning by copying the outlines they have laid with sticks, the children ad
to reproduction of the figures resulting from combinations of tablets; and
these, first to front views, and finally to simple perspective representations
solids and their transformations. As the first step in drawing is to learn
correctly, it is evident that all the exercises, both in gifts and occupations
pare for the use of pencil and chalk. As the mediation of word and object
ing is of vast importance in its reaction on the mind, and as the soul of all
nical processes, it is the indispensable basis of industrial education.

The material for intertwining consists of strips of paper of different c
lengths, and widths, which, folded lengthwise and plaited according to de
rules, represent a great variety of geometric and artistic forms. The plaiti
rule must, however, lead up to free combinations.

In the occupation of mat plaiting the child weaves strips of paper into a l
paper cut into strips, but with a margin left at each end to keep the strips in
Designs are not imitated from patterns, but produced by numerical combina
In this mediation of number and form lies the special significance of the we
exercises, which, however, are also valuable for cultivating the sense of colo

The folding material consists of square, rectangular, and triangular pie
paper, with which a variety of figures are produced by slight modification
few definite ground forms. Through this occupation ideas of sequence and
nection are emphasized and the relation of mathematics to artistic produ
indicated.

In the occupation of cutting, a square or triangle of paper is folded and c
rule; and the pieces into which it is thus separated are combined in symm
forms and mounted on a sheet of paper or cardboard. The child is also en
aged to originate cuts.

By fastening sticks, sharpened at the ends, into peas soaked in water our
worker next produces the skeletons of real objects and of geometric forms.
occupation leads to close analysis of form, connects different solids with thei
responding planes, and prepares for perspective drawing.

While peas work throws into relief the outlines of objects, cardboard m
ing represents their surface boundaries, and clay work brings us back to the
itself. By modifications of and additions to the sphere, cube, and cylinc
variety of objects are represented; and these typical forms are more defi
recognized in the works of nature and of man.

Taken as a whole, the occupations apply the principles suggested by the
and give permanence to their vanishing transformations. It will be observe
particular occupations connect with particular gifts. Thus, pricking, se
and drawing, which are essentially one, connect with the sticks and rings;

twining and mat plaiting connect with the slats; folding and cutting with the tablets and peas work; cardboard and clay modeling with the undivided and divided solids of the first six gifts. It is also noticeable that while the gifts move from the solid to the surface, the line, and the point, the occupations, reversing this movement, develop from point to line, surface, and solid; and that while the determined material of the gifts limits to the combination and arrangement of unchangeable elements, the plastic material of the occupations is increasingly subservient to the modifying thought and touch of the embryo artist.

As has been repeatedly said, the aim of the kindergarten is to strengthen and develop productive activity. But we must be conscious of ideas before we can express them, and we must gain the mastery of material before we can use it as a means of expression. Hence the first use of the gifts is to waken, by their suggestiveness, the mind's sleeping thoughts, and the first use of the occupations to train the eye and the mind to be the ready servants of the will. While the child is still imitative in the occupations, he becomes inventive in the gifts; but as he grows to be more and more a law unto himself, he turns from the coercion of his blocks, tablets, and sticks to obedient paper and clay, and, ultimately outgrowing the simpler occupations, concentrates his interest in the exercises of drawing, coloring, and modeling. These artistic processes, with a technical training according to the very successful Russian plan, might, it seems to me, be profitably introduced into our regular school course.

The symbolism involved in all things—for in nature everything corresponds to spirit, and hence each lower material object is in some sense a key to unlock the perception of a higher, more subtle object—this symbolism is the basis of the intellectual value of the gifts of Froebel. No other educator since Plato's time has understood so well the connection of the child's first activities with his subsequent ones and the significance of what is rudimentary as a preparation for what is to follow.

The following extracts (from another unpublished lecture by Miss Blow) point out this symbolical education as Froebel has intended it:

THE SYMBOLIC PHASE OF EDUCATION.

The instinct of children is to share the life around them. Little girls are eager to help in the work of the house—to sweep, dust, cook, sew, or do anything that older people are doing. The boy will follow his father to the farm, to the forge, to the shop, and is proud and happy to be of the least use. How often do father and mother reject the weak but willing help of the little child! How often do they complain bitterly of the laziness, selfishness, and indifference of the older son or daughter!

As the child's interests and sympathies expand, he comes to notice the different activities of men. With the presentiment that he, too, is born to be a worker in the world, he eagerly watches the world's work; and not content with watching, he tries to imitate. The baby will try to follow the motions of those he sees working. The older child digs and plants, makes houses in the sand, floats his tiny boat on the water, and dams the stream to turn his toy mill. Froebel responds to the effort of the baby by a series of dramatic games representing the movements peculiar to different kinds of work, and to the need of the older child by the gifts and occupations of the kindergarten, through which he is enabled to imitate all kinds of technical and artistic processes.

The importance of industrial education is every day more widely admitted. That Froebel has found the true beginning of technical training is also quite generally recognized. It is one of the important features of the system that a definite training of the hand is begun in babyhood. There are games to strengthen and give freedom to the wrist; there are games to discipline the muscles of the arm; there are games to teach force and flexibility to the fingers. The hand is man's first and most important tool. It can not be too early taught to obey his thought and execute his will. We shall have no large class of skilled workmen until we learn from Froebel how to keep hands from growing clumsy and fingers from getting stiff.

The most fascinating feature of Froebel's games to a thoughtful person is, however, their reaction on thought. They are rooted, every one of them, in the relationship of feeling, action, and thought; they obey without exception that deep law which connects instinct, expression, and insight. How, through their contrasts, the activity of comparison is roused; how they quicken and intensify perception; what presentiments they create of the subtle relationships of sound and

movement: how they stir in the child the sense of proportion: how they sho
soul of harmony in the relations of numbers: how they foreshadow even the
terious correspondences of space and time! All these things and many
others can only be realized by those who, believing that in the night of u
sciousness slumber all the possibilities of the poet and the philosopher, will
patience to watch with Froebel for the dawning of the soul's light.

The opponents of the kindergarten have indulged in a great deal of se
mirth over what they have been pleased to call its false and pernicious symb
Can that be seriously called an educational system, they ask, which allows
to be called fishes and frogs, cats and squirrels; which sees in little mat
sticks trees and lamp-posts and soldiers; which makes the same block stand
house, a chair, and a sheep; and even uses the child's fingers to represe
grandmother, his parents, and his brothers and sisters?

Again, Froebel appeals from the scorn of his critics to the history of th
and the instinctive manifestations of the child. He hears untutored me
the brave man a lion, the meek man a lamb, the cunning man a fox. He
the savage describe his face, not as round, but as moon; and says of his frui
it is sugar cane, instead of saying that it is sweet. He finds among the r
ments of ancient art three cubes standing side by side, inscribed with the
of the Three Graces. He studies reverently Egypt's great unsolved proble
they are images in the Pyramids and the Sphinx. He reads the spirit's faint
tion of immortality in the mysterious phenix. Finding everywhere that ma
sought to express in symbols the truth he feels, but does not understand, he
his eyes upon the child, to seek in his instinctive life another parallel wit
development of mankind. At once he notices the tendency of childhood to
and delight in the most remote resemblances. "Father and mother stars,"
out a 2-year-old baby on seeing in the sky two large, bright stars in the
of a number of small ones. "Dust on the water," explains a boy of 4, as sta
on the seashore, he is blinded by the mist and spray. "Let me catch the
cries the little girl as she watches with delight the flickering reflection of th
light on the wall. Illustrations might be multiplied, but we do not need
We have all seen the boy ride his father's cane, and call it a horse: we
watched many a little girl caress the towel she has rolled and wrapped i
baby: we know how, to the imagination of the child, "the rose leans over t
baby's pillow," and "God sends the little star baby, 'cause the moon was so
in the sky."

The symbolic stage of thought is characterized by the perception of r
blances without abstraction of the qualities in which the resemblance lies.
the child calls the quivering reflection of the sunlight a bird, he shows us th
has been struck chiefly with the bird's swift motion, but at the same time h
learned to consider motion as an abstraction.

So too in the rich play, swimming, and climbing motions th
identifies the cat, the fish, and the squirrel with his ball. His sticks star
trees, lamp-posts, and soldiers through the quality of straightness; and his
fingers and hand suggest the merging of father, mother, and children i
unity of the family.

It is a fact full of deep meaning that the obscure thought or feeling reco
itself in a symbol, and can not recognize itself in a definite and exact refle
We need a mirror, not of what we are, but of what we already dimly see
selves to be. This is the reason that the child's life grows clearer to him th
the life of birds and animals than through the human life around him.
drawn closer to his mother by watching the cat with her kittens, or the m
bird with her young, than he is by seeing other children with their mothers.
no idle curiosity which bids him peer into the bird's nest and watch so int
while the mother bird feeds her young or covers them with her sheltering w
He is fascinated because thus his own life is made objective to him: his own
tion-lines are shown to him in symbol.

The child not only expresses himself symbolically, but is quick to interpr
symbolism of nature. And if, on the one hand, we recognize that he must
sent before he can understand, and know that the analogies which underl
action will in due course develop comparison and abstraction, can we dou
the other that the types of nature will reveal their history and the ma
symbol vanish in the spiritual reality? Looking into the past, we find that
phenomena of nature have been worshiped by men: that the human hear
bowed itself to sun and moon, to mountains and rivers, to beasts, and ev
the most disgusting reptiles. We remember the magicians and lightning of
the mystery of the burning bush, and the pillar of cloud and of fire. We
that to-day the oldest of Christian churches celebrates her mysteries in sym

forms and services; and the universal heart of Christendom concentrates its deepest feelings and intuitions in the symbol of the cross. From all these things may we not infer deep analogies between the outer and the inner world—between the truths God writes in human hearts and those He proclaims through the thousand voices of earth—and believe that by a process we can not trace the mind may move from the perception of the symbol to the conscious realization of the truth symbolized? Such, at least, was Froebel's firm conviction; and we find him, consequently, in many of his little plays directing attention to the natural symbols of great truths—leading the child to love the light, teaching him reverence for unseen forces, making him feel the unity that underlies variety, and stirring within him a prophetic certainty of complete self-recognition.

A single illustration must suffice to indicate this phase of Froebel's thought. To many, I fear, it will prove a stumbling-block; to many others, foolishness. To those only will it commend itself who, realizing that all things are connected, know that nothing is insignificant.

"It is my firm conviction," writes he, "that whatever gives the child pure and persistent pleasure is, however remotely, connected with some deep truth of his nature, and has in it a germ of highest possibilities.

"In the light of this faith, look at the shadow pictures on the wall!

"Between the bright light which shines on the smooth, white wall is thrust a dark object, and straightway appears the form which so delights the child. This is the outward fact. What is the truth which through this fact is dimly hinted to the prophetic mind? Is it not the creative and transforming power of light—that power which brings form and color out of dark chaos, and makes the beauty which gladdens our hearts? Is it not more than this—a foreshadowing, perhaps, of the spiritual fact that our darkest experiences may project themselves in forms that will delight and bless, if back of them, in our hearts, shines the light of God? Stern, bare rocks and forbidding clefts grow beautiful in the sunlight, and the fairest landscape loses life, beauty, and expression in the darkness. Is it not thus also with our lives? Yesterday they seemed to us full of beauty and hope; to-day we see nothing but struggle and pain. Yesterday we felt within us great possibilities; to-day we stagger under doubts and groan in the darkness of our souls. Only clear conviction that it is the darkness within us which makes the darkness without, and that all lives are beautiful when lived in the light of God's idea of them, can restore the lost peace of our souls. Be it, therefore, O mother, your sacred duty to make your child feel early the working both of the outer and the inner light! Let him see in one the symbol of the other, and tracing form and color to their source in the sun, may he learn to trace the beauty and the meaning of his life to their source in God!"

The analogy between light and truth has always been most deeply felt by the most spiritual minds. "The magi said of God that He had light for His body and truth for His soul." The psalmist exclaims, "Thou hast covered Thyself with light as with a garment." Christ tells us that God is Light, and in Him is no darkness at all; and St. John, writing of that state where we shall have done with all symbols, because completely penetrated with the realities they represent, declares that "the city hath no need of the sun, neither of the moon to lighten it."

If the connection is thus real, will it not make itself felt? May not the heart of the child thrill, as the heart of mankind has done, in response to the objective expression of its inward need? May not a childhood of spiritual presentiments best prepare for a manhood of spiritual insights?

As has been already repeatedly stated, Froebel's life and thought were ruled by the idea of organic unity. That all-pervading law of organisms by which they progress from the homogeneous to the heterogeneous, and realize the highest unity through the extreme of variety, was ever present to his mind, and his ideal consequently was the complete development of the individual man for the sake of all men. Therefore, he aimed through self-activity to develop powers, through love to consecrate them to service, through service to lift them into consciousness. To know himself man must feel and know all his relationships; and he learns the sweetness and solemnity of his life only by realizing its connections with nature, with man, and with God.

In view of this vital truth, Froebel insists that from the beginning of life the child shall be led to see and feel connections and dependencies. As these connections exist in the least things they can be shown in the least things, and the habit of mind thus formed will extend itself to greater things as the child's powers strengthen and his experiences enlarge. An instinct of this connection underlies the favorite game of all nurseries, "pat-a-cake," in which the mother shows the child that without the baker he could not have his cake. Froebel seizes this hint and develops it. For the cake the child depends on the baker, the baker on the

miller the miller in the farmer the farmer in the sunshine and the rain. In another game, called grass-mowing, the same general idea is carried out. The motion of the game represents the mowing of the grass; the words tell how the baby loves milk, how the milk comes from the cow, the cow must be fed with the grass the mower reaps, God sends the sunlight and the rain to make the grass grow. In still another play [illegible] the little games the child has learned. I give the words which accompany this game, only adding that the particular motion associated with each separate game is repeated when that game is referred to. Thus the child connects his isolated experiences into a whole, and begins to organize his knowledge.

[illegible]

"[illegible]
[illegible]
[illegible]
[illegible]
[illegible]
[illegible] wreath of varied hue.
[illegible]
[illegible]"

[illegible]

"[illegible] fingers are;
[illegible]
[illegible]
[illegible]
[illegible]
[illegible]
[illegible] greetings
[illegible]
They talk as if they would never rest;
They tell of the basket, the eggs in the nest;
They tell of the doves and the pigeon-house,
How they fly in and out in gay carouse.
They tell of the little fishes gay
In the sparkling water floating away;
The cakes and little patty-cakes;
The target the good brother makes.
Now when they've reviewed their plays all through,
They ask each other what next they shall do.
The fingers say, 'To the steeple we'll go!'
But the little grandmothers they say, 'No!'
In the church door the grandmothers go."

We build up the future on the past; we look back that we may move forward; we grow strong for what is to be by seeing clearly what has been. Hence the great value of history; hence, too, the strength of those who, from time to time, pause in life to collect the results of living.

To most of us, however—perhaps to all of us—the first few years of life are a blank in memory. We wake to consciousness with definite feelings, thoughts, and tendencies. Whence sprang the feelings? How grew the thoughts? What fixed the tendencies? We ask in vain. Over the sources of life roll the silent waves of unconsciousness, and memory loses itself in a beginning when "all was without form and void, and darkness was upon the face of the deep."

The Limits of the Kindergarten as an Educational Appliance.

While the industrial preparation involved in the kindergarten exercises is sufficient justification for its introduction into our school system, it must be confessed that this is far from satisfactory to the enthusiastic disciples of Froebel. They see in the kindergarten the means for the moral regeneration of the human race, and they look upon the industrial phase of its results as merely incidental and of little consequence; and, indeed, they regard those who attempt to justify the kindergarten on an industrial basis as sordid materialists. That they have good reason to claim more than this preparation for manual arts is evident from the preceding extracts, in which Miss Blow has shown how the games, gifts, and occupations are symbolic, and thus propædeutic to subsequent intellectual and moral training. Every conscious intellectual phase of the mind has a previous phase in which it was unconscious and merely symbolic. Feeling, emotion, sensibility—these are names of activities of the soul which become thoughts and ideas by the simple addition of consciousness to them; i. e., the addition of reflection. What smoke is to the clear flame in some sort is instinct to clear rational purpose. Thoughts and ideas preexist, therefore, as feelings and impulses; when later they

are seen as ideas they are seen as having general form or as possessing universality. As feelings they are particular or special, having application only then and there; as thoughts they are seen as general principles regulative of all similar exigencies.

The nursery tale gives the elements of a thought, but in such special grotesque form that the child seizes only the incident. Subsequent reflection brings together the features thus detached and isolated, and the child begins to have a general idea. The previous symbol makes easy and natural the pathway to ideas and clear thought.

Besides the industrial training (through the "gifts and occupations") and the symbolic culture (derived chiefly from the "games"), there is much else in the kindergarten which is common to the instruction in the school subsequently and occupies the same ground. Some disciplines also are much more efficient in the kindergarten by reason of its peculiar apparatus than the same are or can be in the common school.

The instruction in manners and polite habits which goes on in all well-conducted kindergartens is of very great value. The child is taught to behave properly at the table, to be clean in his personal habits, to be neat in the arrangement of his apparatus, to practice the etiquette and amenities of polite life. These things are much better provided for in Froebel's system than elsewhere. Moreover, there is a cultivation of imagination and of the inventive power which possesses great significance for the future intellectual growth. The habits of regularity, punctuality, silence, obedience to established rules, self-control are taught to as great a degree as is desirable for pupils of that age, but not by any means so perfectly as in the ordinary well-conducted primary school. The two kinds of attention that are developed so well in a good school (1) the attention of each pupil to his own task, so absorbed in it that he is oblivious to the work of the class that is reciting, and (2) the attention of each pupil in the class that is reciting to the work of the pupil reciting, the former being the attention of industry and the latter the attention of critical observation, are not developed so well as in the primary school, nor is it to be expected. The freedom from constraint, which is essential in the kindergarten, or in any school for pupils of 5 years of age, allows much interference of each pupil with the work of others, and hence much distraction of attention. It is quite difficult to preserve an exact balance. The teacher of the kindergarten is liable to allow the brisk, strong-willed children to interfere with the others and occupy their attention too much.

As regards imagination and inventive power, it is easily stimulated to an abnormal degree. For if it is accompanied by conceit, there is a corresponding injury done to the child's faith and reverence which must accompany his growth if he would come to the stores of wisdom which his race has preserved for him. The wisest men are those who have availed themselves most of the wisdom of the race. Self-activity, it is true, is essential to the assimilation of the intellectual patrimony; but it is a reverent spirit only that can sustain one in the long labor of mastering and acquiring that patrimony.

The cultivation of language—of the power of expression—is much emphasized by the advocates of the kindergarten, and, I believe, with fair results.

There is a species of philosophy sometimes connected with the system which undoubtedly exercises a great influence over the minds of the followers of Froebel. It is, apparently, a system founded on a thought of Schelling—the famous "identity system"—which made the absolute to be the indifference or identity of spirit and nature. Its defect is that it deals with antitheses as resolvable only into "indifference" points; hence the highest principle must be an unconscious one, which makes its philosophy a pantheistic system when logically carried out. But Froebel does not seem to have carried it out strictly. He uses it chiefly to build on it as a foundation his propædeutics of reflection, or thinking activity. Antith-

esis, or the doctrine of opposites (mind and nature, light and darkness, sweet and sour, good and bad, etc.), belongs to the elementary stage of reflection. It is, however, a necessary stage of thought (although no ultimate one) and far above the activity of sense perception. But, compared with the thinking activity of the comprehending reason, it is still very crude. Moreover, from the fact that it is not guided by a principle above reflection, it is very uncertain. It is liable to fall from the stage of reflection which cognizes antithesis (essential relation) to that which cognizes mere difference (nonessential relation). Such imperfection I conceive to belong rather to some of the interpreters of Froebel's philosophic views than to Froebel's system as he understood it. It is certainly not a fault of his pedagogics. His philosophy is far deeper than that of Pestalozzi, while his pedagogical system is far more consistent, both in theory and in practice.

As regards the claimed transcendence of the system over all others in the way of moral development, I am inclined to grant some degree of superiority to it, but not for intrinsic reasons. It is because the child is then at an age when he is liable to great demoralization at home and is submitted to a gentle but firm discipline in the kindergarten that the new education proves of more than ordinary value as a moral discipline. The children of the poor, at the susceptible age of 5 years, get many lessons on the street that tend to corrupt them. The children of the rich, meeting no wholesome restraint, become self-willed and self-indulgent. The kindergarten may save both classes and make rational self-control take the place of unrestrained, depraved impulse.

But the kindergarten itself has dangers. The cultivation of self-activity may be excessive and lead to pertness and conceit. The pupil may get to be irreverent and overbearing—hardened against receiving instruction from others. In fact, with a teacher whose discernment is dimmed by too much sentimental theory, there is great danger that the weeds of selfishness will thrive faster among the children than the wholesome plants of self-knowledge and self-control. The apotheosis of childhood and infancy is a very dangerous idea to put in practice. It does well enough in Wordsworth's great ode, as a sequence of the doctrine of preexistence; and it is quite necessary that we should, as educators, never forget that the humblest child—nay, the most depraved child—has within him the possibility of the highest angelic being. But this angelic nature is only implicit, and not explicit, in the child or in the savage or in the uneducated. To use the language of Aristotle, the undeveloped human being is a "first entelechy," while the developed, cultured man is a "second entelechy." Both are, "by nature," rational beings; but only the educated, moral, and religious man is rational actually. "By nature" signifies "potentially" or "containing the possibility of."

There is no technical expression in the history of pedagogy with which more juggling has been done than with the word "nature." As used by most writers, it signifies the ideal or normal type of the growth of anything. The nature of the oak realizes itself in the acorn-bearing monarch of the forest. The nature of man is realized in the angelic, godlike being whose intellect, and will, and emotions are rational, moral, and pervaded by love. We hear the end of education spoken of as the harmonious development of human nature, physical, intellectual, moral, and affectional. This "nature," in the sense of ideal or normal type, is, however, liable to be confounded with "nature" in the opposite sense, viz, nature as the external world (of unconscious growth). This confusion is the worst that could happen, when we are dealing with the problem of human life; for man, by nature (as unconscious growth), is only the infant or savage, the mere animal, and his possible angelic "nature" is only possible. Moreover, this possibility never will become actuality except through his own self-activity; he must make himself rational, for nature as the external world will never do this for him. Indeed, where nature as the external (unconscious) world is most active in its processes—say, in the torrid zone—there the development of man will be most

retarded. Nature as external world is a world of dependence, each thing being conditioned by everything else, and hence under fate. The humblest clod on the earth pulsates with vibrations that have traveled hither from the farthest star. Each piece of matter is necessitated to be what it is by the totality of conditions. But the nature of man—human nature—must be freedom, and not fate. It must be self-determined, and not a mere "thing" which is made to be what it is by the constraining activity of the totality of conditions. Hence, those who confuse these two meanings of "nature" juggle with the term, and in one place mean the rational ideal of man—the self determining mind—and in another place they mean a thing, as the product of nature as external world. The result of this juggling is the old pedagogical contradiction found in Rousseau throughout, and now and then in the systems of all other pedagogical reformers—Pestalozzi in particular, and even in Locke before Rousseau.

To become rational, man must learn to practice self-control and to substitute moral purpose for mere impulse. Man inherits from nature, in time and space, impulses and desires; and, as subject to them, he is only a Prometheus Vinctus—a slave of appetite and passion, like all other animals. The infant begins his existence with a maximum of unconscious impulse and a minimum of conscious, rational, moral purpose. The disciple of Froebel who apotheosizes infancy and says, with Wordsworth:

> Heaven lies about us in our infancy,

and who thinks that the child is a—

> Mighty prophet! Seer blest,
> On whom those truths do rest
> Which we are toiling all our lives to find,

is prone to regard the kindergarten as a "child's paradise," wherein he should be allowed to develop unrestrainedly, and the principle, laissez faire—"let him alone"—is to fill the world with angels.

This belief in the perfection of nature is the archheresy of education. It is the more dangerous because it has a side of deepest truth—the truth which makes education possible, viz, the truth that man possesses the capacity for self-regeneration—the capacity of putting off his natural impulses and desires, his animal selfishness, and of putting on righteousness and holiness. His ideal nature must be made real by himself in order to be. His real nature, as a product of time and space, must be annulled and subordinated, and his ideal nature be made real in its place.

The child as individual, and without availing himself of the help of his fellows, is a mere slave, a thing, a being controlled by fate. Through participation with his fellow-men united into institutions—those infinite, rational organisms, the product of the intellect and will of the race conspiring through the ages of human history and inspired by the Divine purpose which rules all as Providence—through participation in institutions, man is enabled to attain freedom, to complement his defects as individual by the deeds of the race; he subdues nature in time and space and makes it his servant; he collects the shreds of experience from the individuals of the race and combines them into wisdom, and preserves and transmits the same from generation to generation; he invents the instrumentalities of intercommunication—the alphabet, the art of printing, the telegraph and railroad, the scientific society, the publishing house, the bookstore, the library, the school, and, greater than all, the newspaper. The poor, squalid individual, an insignificant atom in space and time, can, by the aid of these great institutions, lift himself up to culture, and to the infinitude of endless development. From being mere individual, he can become generic, i. e., realize in himself the rationality of the entire species of the human race. By education we mean to do exactly this thing; to give to the individual the means of this participation in the aggregate labors of all humanity.

Hence we are bound to consider education practically, as a process of initiating the particular individual into the life of his race as intellect and will power. We must give to a child the means to help himself and the habit and custom of helping himself; to participate in the labors of his fellow-men, and to become a contributor to the store created by mankind. Institutions: the family; civil society, with its arts and trades and professions and establishments, schools, etc.; the state, with its more comprehensive organizations, and, finally, the church. These are greater than the individual, and they are products of his ideal nature, and exist solely as means whereby the individual may develop his ideal.

The kindergarten, then, has the same general object that the school has had all along—to eliminate the merely animal from the child, and to develop in its place the rational and spiritual life.

Now, as regards the science of the kindergarten, there is one more consideration which is too important to pass by—the theory of play as an educational element.

The school had been too much impressed with the main fact of its mission, viz., to eliminate the animal nature and to superinduce the spiritual nature, to notice the educative function of play. Froebel was the first to fully appreciate this and to devise a proper series of disciplines for the youngest children. The old régime of the school did not pay respect enough to the principle of self-activity. It sacrificed spontaneity in an utterly unnecessary manner, instead of developing it into rational self-determination. Hence it produced human machines, governed by prescription and conventionality, and but few enlightened spontaneous personalities who possessed insight as well as law-abiding habit. Such human machines, governed by prescription, would develop into lawbreakers or sinners the moment that the pressure of social laws was removed from them. They did not possess enough individuality of their own. They had not assimilated what they had been compelled to practice. They were not competent to readjust themselves to a change of surroundings.

Now, in play the child realizes for himself his spontaneity, but in its irrational form of arbitrariness and caprice. In its positive phase he produces whatever his fancy dictates; in its negative phase he destroys again what he has made, or whatever is his own. He realizes by these operations the depth of originality which his will power involves—the power to create and the power to destroy. This will power is the root of his personality—the source of his freedom. Deprive a child of his play, and you produce arrested development in his character. Nor can his play be rationalized by the kindergarten so as to dispense altogether with the utterly spontaneous, untamed play of the child, wherein he gives full scope to his fancy and caprice, without depriving his play of its essential character and changing it from play into work. Even in the kindergarten, just as in the school, there must be prescription. But the good kindergarten wisely and gently controls in such manner as to leave room for much of the pure spontaneity of play. It prescribes tasks, but preserves the form of play as much as is possible. If the child were held to a rigid accountability in the kindergarten for the performance of his task, it would then cease to be play and become labor. Labor performs the prescribed task. Play prescribes for itself. The attempt to preserve the form of self-prescription for the child in his tasks is what saves the kindergarten from being a positive injury to the child at this tender and immature age. It is the preservation of the form of play, and at the same time the induction of the substance of prescription, that constitutes what is new and valuable in Froebel's method of instruction. There is a gentle insinuation of habits of attention, of self-control, of action in concert, of considerateness toward others, of desire to participate in the common result of the school, that succeeds in accomplishing this necessary change of heart in the child—from selfishness to self-renunciation—without sacrificing his spontaneity so much as is done in the old-fashioned primary school. And he gets large measures of the benefits of the school that he would

have lost had he remained at home in the family. The child, too, at this period of life has begun to experience a hunger for the more substantial things of social life, and the family alone can not satisfy his longings. The discovery of Froebel gives the child what is needed of the substantial effects of the school without the danger of roughly crushing out his individuality at the same time.

THE PRACTICAL CONDITIONS NECESSARY FOR THE SUCCESS OF THE KINDERGARTEN.

After we have decided in the affirmative the essential questions relative to the reasonableness of the course of study and discipline of the kindergarten, its suitability to the age of the children, its effect upon the education that follows it, we come to the subsidiary questions regarding expense, training of teachers, and the details of management. These questions are not important, unless the decision is reached that the kindergarten theory is substantially correct. If it is found to be a valuable adjunct to the school, then we must solve the practical problems of how to introduce it into the public-school system. The problem is, how to meet the expense. If the traditional form of the kindergarten be adopted, that of one teacher to each dozen pupils, and this constituting an isolated kindergarten, the annual cost of tuition would be from $50 to $100 per pupil, a sum too extravagant to be paid by any public-school system. The average tuition per pupil in public-school systems of the United States ranges from $12 to $20 for the year's schooling of two hundred days. No school board would be justified in expending five times as much per pupil for tuition in a kindergarten as it expended for the tuition of a pupil in the primary or grammar school.

If it is necessary to limit the number of pupils per teacher to 12 or 20, while in the primary school each teacher can manage and properly instruct 50 or 70, it becomes likewise necessary to invent a system of cheaper teachers. At once the Lancasterian system, or the "monitorial" system, suggests itself as a model for the organization of the cheap kindergarten. The kindergarten shall be a large one, located in a room of ample size to hold 5 to 10 tables, each table to have 15 children attending it, and presided over by a novitiate teacher; and the whole room shall be placed under the charge of a thoroughly competent teacher of experience and skill and well versed in the theory and practice of Froebel's system. The director of the kindergarten must be a well-paid teacher, receiving as much as the principal of a primary school, with 2 assistants. Her assistants, the "novitiate teachers," are learners of the system. The first year they shall be volunteers, and receive no salary; the second year, or as soon as they pass the first examination in theory and practice of the kindergarten, they are to receive a small salary as "paid assistants." After a year's service as paid assistants they may pass a second examination, and, if found competent, be appointed directors, and receive a higher salary.

In the St. Louis kindergartens the number of 60 pupils entitles the director to 1 paid assistant, and there is 1 additional appointed for each 30 pupils above that number. Thus there would be a director and 4 paid assistants if the kindergarten had 150 pupils. (The director would, in St. Louis, receive $350 per annum, and each paid assistant $125 per annum. The cost of tuition, based on teachers' salaries, would be $850 per annum for the 150 pupils, being less than $6 per annum for each.)

Besides the salaried teachers of the kindergarten, it is expected that there will be an equal or greater number of volunteers. In order to make it worth while for volunteers to join the system, as well as to secure the development of the salaried teachers, it is necessary to have two persons of superior ability that can give instruction once a week on the theory and practice (the "gifts and occupations") of Froebel's system. A young woman will find so much culture of thought to be derived from the discussion of Froebel's insights and theories, and so much pecul-

iarly fitting experience from her daily class in the kindergarten—experience tha will prove invaluable to her as a wife and mother—that she will serve her appren ticeship in the kindergarten gladly, though it be no part of her intention to follo teaching as a vocation.

It is a part of the system, as an adjunct to the public schools, to educate youn women in these valuable matters relating to the early training of children. have thought that the benefit derived by the 200 young women of the St. Loui kindergartens from the lectures of Miss Blow to be of sufficient value to compen sate the city for the cost of the kindergartens. A nobler and more enlightene womanhood will result, and the family will prove a better nurture for the child

Here we come upon the most important practical difficulty in the way of th general introduction of the kindergarten. If the teachers are no better than th average mothers in our families, if they are not better than the average primar teacher, it is evident that the system of Froebel can not effect any great reform i society. "It is useless to expect social regeneration from persons who are no themselves regenerated."

In our St. Louis work we have been very fortunate in having a lady of grea practical sagacity, of profound and clear insight, and of untiring energy to organ ize our kindergartens and instruct our teachers. Her (Miss Susan E. Blow's) dis interested and gratuitous services have been the means of securing for us a syster that now furnishes its own directors, assistants, and supervisors.

There is another important point connected with the economy of the kindergar ten. The session should not last over three hours for the children of this age Hence each room permits two different sessions to be held in it per day, one in th morning and one in the afternoon, thus accommodating double the number o pupils. In some cases, where the teacher has attained experience and strengt sufficient, she teaches in both sessions, and receives a higher grade of salary fo the work. (In St. Louis, as already mentioned, directors receive $600 for tw sessions per day, and $350 for one session; paid assistants receive $125 for one ses sion and $200 per annum for two daily sessions.)

The furniture of the kindergarten is made up of small, movable chairs and smal tables, each one capable of accommodating two children—the surface of the tabl being marked off into divisions 1 inch square. It is better to use the small table than large ones that will accommodate a whole class, for the small ones may b moved easily and combined into large ones of any desirable size, and may b readily arranged into any shape or figure, and placed in any part of the room, b the children themselves. It is necessary to use the floor of the room during on exercise each day for the games, at which time all the children are collected "o the circle;" at this time it may be desirable to remove the tables to the sides o the room, and with small tables this can be easily accomplished. Again, in th absence of one of the teachers, it may become necessary to combine two classe into one, uniting two tables. The small tables are, therefore, an important iten in the economy of the kindergarten.

With these suggestions, I leave the subject, believing that they are sufficient t justify the directors of our public schools in making the kindergarten a part o our school system. The advantage to the community in utilizing the age from to 6; in training the hand and eye; in developing habits of cleanliness, politeness self-control, urbanity, industry; in training the mind to understand numbers an geometric forms, to invent combinations of figures and shapes, and to represen them with the pencil—these and other valuable lessons in combination with thei fellow-pupils and obedience to the rule of their superiors—above all, the usefu suggestions as to methods of instruction which will come from the kindergarte and penetrate the methods of the other schools—will, I think, ultimately prevai in securing to us the establishment of this beneficent institution in all the cit school systems of our country.

CHAPTER XX.

SOME RECENT CONTRIBUTIONS OF BIOLOGY, SOCIOLOGY, AND METALLURGY TO THE CURRICULUM OF COLLEGES ENDOWED BY THE FEDERAL GOVERNMENT FOR THE BENEFIT OF AGRICULTURE AND THE MECHANIC ARTS.[1]

BIOLOGICAL: (*a*) The foundation of agricultural chemistry and the inspiration to found experiment stations, directly due to Theodore de Saussure in 1804—The value of one experiment—The food taken by the plant from the air—The contest about the source of nitrogen—The microbe or ferment—The communication addressed by Messrs. Schloesing and Müntz to the French Academy of Sciences describing their discovery of a nitrogenous ferment in the soil—Discovery of the microbe causing this "fermentation," by Hellriegel and Willfarth, and further proof by Schloesing, jr., and Laurient—The food the plant takes from the soil. (*b*) The formation of vegetable mold and geological formations now in process in the United States through the work of coral animals on the coast of Florida and of lumbermen on the mountain sides—The agricultural differences (as shown by experiment at the University of Halle) between a soil with and a soil without earthworms—The power of the actinic or photographic rays of the sunbeam upon organic acids and in general upon vegetation—Epitome of the Rothamsted experiments and results during the last half century. (*c*) The plant as a vital machine seemingly endowed with a crude reflex activity or "irritability"—The vegetable cell or cell with a cellulose sac—The dynamics of cell growth—The movement and "instincts" of the root, leaf, and flower—Inheritance.

SOCIOLOGICAL: (*a*) The ebb and flow of population not a new phenomena—Efforts of society to interfere with such exchange or regulate it—Ancient slavery—Mediæval serfdom—Modern education. (*b*) Instincts at the bottom of migrations and the production of a proletarate—Charts representing the age of the populations of great cities. (*c*) The birth rate and death rate of city and country compared—Effect of country life on fecundity—Effect of city life on infants and in increasing illegitimacy. (*d*) Cooperation a form of trades unionism combined with agricultural capitalistic production—Value of the effort if considered from the economic rather than the political side—Cooperation in California (irrigation works)—In France, Germany, and Switzerland—Present condition of peasant life in Russia.

METALLURGICAL: The iron age the golden age. (*a*) Scientific engineering—Mining engineering and quick returns—Subterranean metalliferous deposits as a public resource and conservative treatment. (*b*) Legislation in the United States on the ownership of mineral deposits—In England and France—The protection of the miner—Tariff laws of the United States (in tabular form) regarding minerals and crude forms of metals since 1789. (*c*) Improvements in mining—The rock drill—The air-driven coal cutter, pick form, circular-saw form, and chisel form—The old and new methods of conveying the ore to the surface—The blast furnace and its development: Egyptian, Catalan, open-topped, closed tops with hot blast, etc.—The Siemen's "gas producer"—The creation of "metallurgical metals." (*d*) The mining academies of Saxony, France, and England—The evident imitation of the English school by American schools—The course of such schools and the positions circumstances have forced them to take in the past—The curricula considered.

NOTE A.—Professor Lockyer's meteoric hypothesis as to the formation of suns and worlds.

NOTE B.—Professor Drummond's theory of the function of the "African white ant" in agriculture and the formation of the vegetable soil of the valley of the Nile.

NOTE C.—Professor Dewar's apparatus for consolidating common air, with some account of the same.

Several years before the formation of the Association of Agricultural Colleges and Experiment Stations a report was made to the committee on technical instruction of the National Council of Education by a president of a western agricultural

---

[1] By Mr. Wellford Addis, specialist for obtaining and collecting information regarding colleges for the benefit of agriculture and the mechanic arts.

college. The title of the report is Agricultural Schools: Their Objects, Methods, and Equipments. In the course of his argument the reporter remarked that "agricultural colleges have for their aim the promotion of intelligence in farming" and if such examples of body, mind, and sympathies as shall give strength for the task of elevating agriculture while the everyday surroundings add to the natural curiosity about seeds, soils, moisture, heat, germination, and fertilization, variation in plant and animal, adaptation of parts and forms. Botany, chemistry, mineralogy, entomology, comparative anatomy, physiology, zoology, and geology make a series so full of constant allegiances to previous curiosity as to give new zest to the problems of farm life.

Upon the publication of the report one of the members of the Council inquired whether the agricultural schools had investigated certain questions in agricultural chemistry which he deemed to be of great practical importance and to which he had seen no satisfactory answer. One of these questions was: "Does the deprivation of light have an effect to cause air to deposit some of its nitrogen?" He also wanted an explanation of the reason why unmilled land produced a sparse vegetation, while the earth overturned and frequently stirred was far more fruitful. He thought (speaking in 1890) that there should be far more experimenting among farmers and in agricultural colleges, and he also thought that when youth were properly instructed in agricultural schools they would be able to show the fallacies of the ox-tax theory. In reply to the inquiry, the reporter, President Fairchild, remarked that his college had been conducting experiments for two years upon the source of nitrogen, and when the experiments were completed a report thereon would be made, as the problem is a very complex one from the many modifying circumstances.

This report to the national council in 1888 was upon education in agriculture, and in such a report it would have been out of place to have spoken of the other group of technical subjects which Congress had joined with agricultural, that is to say, the engineering professions, when that body founded the schools for the benefit of agriculture and the mechanic arts. But in treating of such double-purposed colleges it would be somewhat anomalous for this Bureau to speak of them as though they were wholly agricultural colleges. As poorly as the study of agriculture had flourished in the land-grant colleges up to 1890, it was in a better position than the study of mining and metallurgical engineering. "We Germans," said a professor of that nationality, "have a large export trade in chemists." Thus a country filled with natural resources and home and foreign capital to develop them had no institution that could compare in status with the Royal Mining Academy of a little German State no bigger than the half of Massachusetts.

PART I.—BIOLOGICAL CONCEPTIONS.

Agriculture is both a science and an art, and the knowledge of all the conditions of vegetable life forms its scientific basis. If, then, it be asked, What is the reason one kind of plant succeeds in a field where another fails? the question belongs to the science of agriculture; but if it be asked, What measures are to be taken to preserve the fertility of a field or to render it fertile? that is a question put by the art to the science.[1]

The confusing federation of isolated sciences which form the course in agriculture in American colleges interferes with the study of that science. It is impossible to deny that the study lacks unity. There is a department of practice or labor, of chemistry, of physics, of botany, and the other classificatory sciences in every agricultural school. This separation is, indeed, unavoidable, but the work of these departments appears to be unfocused.

[1] Liebig, Familiar Letters on Chemistry, 1843, p. 125 and 126 N. Y. ed.

In the following matter it will be confidently assumed that the advance in biological study has cleared the way for a conception of a course in the theory of agriculture that is more homogeneous than the mere parallelism of a number of abstract sciences, the application of which to agriculture is recognized, but not shown. In thus recalling and in collating certain facts in regard to the science of agriculture, it will be considered, for the sake of brevity and clearness, to be—

1. The theories about the chemical changes whereby manure is changed into food ("fertility").

2. The circumstances that produce fertility.

3. The self-activity of plants in availing themselves to the utmost of the possibilities of their surroundings in order to perfect the hereditary instincts produced by the natural or artificial impregnation of the flower whence comes the seed.

In pursuing the course thus marked out the conceptions by which chemists and botanists have represented to themselves and to the public the manner in which plants grow and how they feed will be spoken of, then the effect on the soil of a long continuous growing and feeding of agricultural plants, and finally the manner in which plants behave as individuals endowed with the energy of sustaining themselves and perpetuating their kind and how new kinds of plants are created. But before speaking of a century of inconclusive but epoch-making hypotheses about vegetable nutrition, a half a century of facts which are true of Rothamsted at least, and a quarter of a century of the study of natural selection and the variation of plants under domestication, we must speak of two experimenters to whose sagacity the idea of an agricultural chemistry built on facts, the inspiration to found a Rothamsted, and the idea of a natural selection are due.

In 1804 M. Theodore de Saussure published the first and most important body of original and indisputable facts concerning agricultural chemistry ever issued. It bore the title "Recherches chimiques sur la végétation," and as it is not a work of the imagination, it may be described for those who like a lively diction and the brilliant effects found in Mr. Jules Verne's Trip to the Moon as a very dull book indeed. M. de Saussure did not wish to amuse. He desired to avoid all questions to which experiment could give no answer, for "in natural history facts alone lead to the truth," and though he candidly acknowledges that the road he has chosen is dry and tiresome, he justifies his course on the ground that it alone will lead to the development of agriculture.[1]

About 1860 Mr. Darwin began publishing his investigations in vegetable forces, and in doing so apologizes for his intrusion into the field of botany. "The hybridization and movement of plants, he says, ought to have been treated by a professed botanist";[2] but it was necessary that the author of the Descent of Man should seek instances in the vegetable kingdom to verify his hypothesis—the so-called Darwinian hypothesis—of natural selection.[3] These investigations of Mr. Darwin are epoch making, but seem not yet to be classed as a part of agricultural science. The future may show that to ascertain the difference between the vigor of a weed and of a "useful plant" is a very important thing for agricultural science to do.

THE CONVERSION OF GASES AND EARTHS INTO FOOD.

Before the dawn of the century now drawing to a close, Bonnet,[4] of Geneva, had discovered that the leaves of plants give off a gas; Priestley, an Englishman, the discoverer of oxygen, that the gas is oxygen;[5] Ingenhouse, an Anglicized Hol-

college. The title of the report is Agricultural Schools: Their Objects, Methods, and Equipments. In the course of his argument the reporter remarked that "agricultural colleges have for their aim the promotion of intelligence in farming" and of "such discipline of body, mind, and sympathies as shall give strength for the task of elevating agriculture while the everyday surroundings add to the natural curiosity about seeds, soils, moisture, heat, germination, and fertilization, variation in plant and animal, adaptation of parts and forces. Botany, chemistry, mineralogy, entomology, comparative anatomy, physiology, zoology, and geology make a series so full of constant adaptations to previous curiosity as to give new zest to the problems of farm life."

Upon the conclusion of the report one of the members of the Council inquired whether the agricultural schools had investigated certain questions in agricultural chemistry which he deemed to be of great practical importance and to which he had seen no satisfactory answers. One of these questions was, "Does the deprivation of light have an effect to cause air to deposit some of its nitrogen?" He also wanted an explanation of the reason why untilled land produced a sparse vegetation, while the earth overturned and frequently stirred was far more fruitful. He thought (speaking in 1888) that there should be far more experimenting among farmers and in agricultural colleges, and he also thought that when youth were properly instructed in agricultural schools they would be able to show the fallacies of the one-tax theory. In reply to the inquiry, the reporter, President Fairchild, remarked that his college had been conducting experiments for two years upon the source of nitrogen, and when the experiments were completed a report thereon would be made, as the problem is a very complex one from the many modifying circumstances.

This report to the national council in 1888 was upon education in agriculture, and in such a report it would have been out of place to have spoken of the other group of technical subjects which Congress had joined with agricultural, that is to say, the engineering professions, when that body founded the schools for the benefit of agriculture and the mechanic arts. But in treating of such double-purposed colleges it would be somewhat anomalous for this Bureau to speak of them as though they were wholly agricultural colleges. As poorly as the study of agriculture had flourished in the land-grant colleges up to 1890, it was in a better position than the study of mining and metallurgical engineering. "We Germans," said a professor of that nationality, "have a large export trade in chemists." Thus a country filled with natural resources and home and foreign capital to develop them had no institution that could compare in status with the Royal Mining Academy of a little German State no bigger than the half of Massachusetts.

PART I.—BIOLOGICAL CONCEPTIONS.

Agriculture is both a science and an art, and the knowledge of all the conditions of vegetable life forms its scientific basis. If, then, it be asked, What is the reason one kind of plant succeeds in a field where another fails? the question belongs to the science of agriculture; but if it be asked, What measures are to be taken to preserve the fertility of a field or to render it fertile? that is a question put by the art to the science.[1]

The confusing federation of isolated sciences which form the course in agriculture in American colleges interferes with the study of that science. It is impossible to deny that the study lacks unity. There is a department of practice or labor, of chemistry, of physics, of botany, and the other classificatory sciences in every agricultural school. This separation is, indeed, unavoidable, but the work of these departments appears to be unfocused.

[1] Liebig, Familiar Letters on Chemistry, 1843, p. 125 and 126 N. Y. ed.

In the following matter it will be confidently assumed that the advance in biological study has cleared the way for a conception of a course in the theory of agriculture that is more homogeneous than the mere parallelism of a number of abstract sciences, the application of which to agriculture is recognized, but not shown. In thus recalling and in collating certain facts in regard to the science of agriculture, it will be considered, for the sake of brevity and clearness, to be—

1. The theories about the chemical changes whereby manure is changed into food ("fertility").

2. The circumstances that produce fertility.

3. The self-activity of plants in availing themselves to the utmost of the possibilities of their surroundings in order to perfect the hereditary instincts produced by the natural or artificial impregnation of the flower whence comes the seed.

In pursuing the course thus marked out the conceptions by which chemists and botanists have represented to themselves and to the public the manner in which plants grow and how they feed will be spoken of, then the effect on the soil of a long continuous growing and feeding of agricultural plants, and finally the manner in which plants behave as individuals endowed with the energy of sustaining themselves and perpetuating their kind and how new kinds of plants are created. But before speaking of a century of inconclusive but epoch-making hypotheses about vegetable nutrition, a half a century of facts which are true of Rothamsted at least, and a quarter of a century of the study of natural selection and the variation of plants under domestication, we must speak of two experimenters to whose sagacity the idea of an agricultural chemistry built on facts, the inspiration to found a Rothamsted, and the idea of a natural selection are due.

In 1804 M. Theodore de Saussure published the first and most important body of original and indisputable facts concerning agricultural chemistry ever issued. It bore the title "Recherches chimiques sur la végétation," and as it is not a work of the imagination, it may be described for those who like a lively diction and the brilliant effects found in Mr. Jules Verne's Trip to the Moon as a very dull book indeed. M. de Saussure did not wish to amuse. He desired to avoid all questions to which experiment could give no answer, for "in natural history facts alone lead to the truth," and though he candidly acknowledges that the road he has chosen is dry and tiresome, he justifies his course on the ground that it alone will lead to the development of agriculture.[1]

About 1860 Mr. Darwin began publishing his investigations in vegetable forces, and in doing so apologizes for his intrusion into the field of botany. "The hybridization and movement of plants, he says, ought to have been treated by a professed botanist";[2] but it was necessary that the author of the Descent of Man should seek instances in the vegetable kingdom to verify his hypothesis—the so-called Darwinian hypothesis—of natural selection.[3] These investigations of Mr. Darwin are epoch making, but seem not yet to be classed as a part of agricultural science. The future may show that to ascertain the difference between the vigor of a weed and of a "useful plant" is a very important thing for agricultural science to do.

THE CONVERSION OF GASES AND EARTHS INTO FOOD.

Before the dawn of the century now drawing to a close, Bonnet,[4] of Geneva, had discovered that the leaves of plants give off a gas; Priestley, an Englishman, the discoverer of oxygen, that the gas is oxygen;[5] Ingenhouse, an Anglicized Hol-

lander, that light causes the gas to flow out,[1] and Senebier,[2] again a Genevese, that the gas discarded is a waste product which the leaf, so to speak, pulls out from the chemical compound which enters it as carbonic-acid gas. Thus the basis for a chemistry of agriculture was laid, and upon this foundation Saussure, another citizen of Geneva, began to build the science of agriculture.[3]

Mr. de Saussure's problem was this: Is Bonnet right in claiming that plants are fed entirely by air and water? Do they really make the chemicals contained in their structure or are they fed entirely by matter in the shape of gas?[4] He sought the answer in the ashes of plants, and he was "astonished to find that three-fourths of the ashes of green herbaceous plants are alkaline salts."[5] My life, he says in substance, was not long enough to investigate this matter thoroughly by studying the ashes of different plants and different parts of the same plant at different periods of a plant's existence. But even this regret bore fruit, for it inspired Sir John Lawes to undertake the work of long breath now so famous as the "Rothamsted Experiments,"[6] while the experiments he did make have given rise to the theories or quasi theories of Boussingault, who stood out for the overwhelming value of the nitrogenous (ammoniacal) matters of manure; of Liebig, who stood out for the value of the mineral matter it should contain, the air furnishing ammonia,[7] and of Pasteur, who stood out for microbous ferments, which, in their action, perhaps robbed the air of its nitrogen and turned it over to the plant chemically as Liebig[8] contended; perhaps broke up the insoluble compounds of nitrogen which Liebig showed were in the soil as the leaf takes out carbon from the carbonic acid of the air; perhaps merely converted the farmyard manure into "ammonia salts," as Boussingault, without dreaming of a microbe, thought[9] in one way and Saussure in another.[10]

In view of these statements it may be suggested that the starting point in the science of agriculture is the work of M. de Saussure, entitled Recherches chimiques sur la végétation, and that their author is the father of agricultural science.[11] It

[3] The investigations with which I have busied myself in this work (Recherches chimique sur la végétation) have for their object the influence of water, air, and humus upon the vegetation (p i). My end was to learn (by examining the ashes of burned plants) the law of their structure, not only by examining the ashes of different plants, but of the different parts of the same plant and at different periods of its growth. My life was too short to thoroughly carry out such a work and I deemed it sufficient to follow general investigations (p. 312).

[10] Recherches chimiques, pp. 207, 205. Boussingault thought that Saussure magnified the amount of nutriment furnished by the air.

[11] Professor Dehérain claims this distinction for his friend, Boussingault (L'œuvre agricole de M. Boussingault, in Revue Scientifique, July 9, 1887). Likewise Professor Pettinkoffer, of the University of Munich, claims the same distinction for his friend and colleague, Baron Liebig. It seems natural, to say the least, to place Saussure as the founder of agricultural chemistry and of the proper method of investigation, while to the genius of Liebig may be given the honor of throwing the facts into a pedagogic form. Such ideas can in no way interfere with the vast merit of M. Boussingault in his researches on nitrogen as announced by the great chemist himself in telling M. Dehérain that when he began "no one knew how much azote (nitrogen) is in hay." Saussure's problem was to find how much air stuff there is in hay, and Liebig's to tell how it got there.

was he who first used the direct method in the chemical observation of plant growth, though Boussingault claims for himself the honor of applying with profit the indirect method of procedure which is called by the ambiguous name of elementary analysis (analyse élémentaire).[1]

As there will be frequent mention here of experimentation, let us ask, What is an experiment? "When I consider," says Sir Humphry Davy, "the variety of theories which may be formed on the slender foundation of one or two facts, I am convinced that it is the business of the true philosopher to avoid them [theories] altogether; it is more laborious to accumulate facts than to reason concerning them, but one good experiment is of more value than the ingenuity of a brain like Newton's." Despite this slashing argument it is to be observed that it may require a brain like Newton's to tell what an experiment is worth after it has been made, and it may not be too delicate a point to raise to ask whether it is ignorance or a theory which starts an experiment; and if it be ignorance, how can the experiment be intelligent, and if it be theory, how can the experiment—whether positive or negative, and however well done—be intellectually better than its source? In the course of this paper an attempt will be made to answer this question. At present the value of a single experiment may be ascertained from the following relation:

About the close of the last century one Lampadius made the following test: He constructed of boards five adjacent compartments or boxes, each box being 2 feet square and 1 foot deep. In one of these he put clay, into another sand, into another magnesia soil, into another lime soil, and into the remaining one garden soil, having, it should be added, previously mixed 8 pounds of cow manure with the material placed in each box. Upon these five soils he sowed rye, and in due course of time and of the necessary incinerations of the harvest he found that the ashes yielded by the plant products of each box of soil were made up of the same kind of substance. He forthwith concluded that these substances had been formed without any reference to the nature of the soil, but he forgot to note the possible effect that 8 pounds of the same substance he had mixed with the earth contained in each box might have upon his conclusion. It must be remembered that it was only a few years before that Lavosier had triumphantly disproved the idea of the savants of the eighteenth century that water makes soil.[2]

We can form three hypotheses about the source of plant food. It may be conjectured that it is manufactured by the plant itself, or that it is merely appropriated by the plant ready-made, either from the air by its leaves or from the earth through its roots. Of these let us begin with the atmosphere which is the sphere of the leaf. The following description will give some conception of this organ:

The apparatus of the leaf: Examined under the microscope with very high powers the leaf of a tea plant presents the following characteristics: The upper skin (fig. 5) is formed of polygonal cells, with their cell walls or cases slightly undulating. The skin on its outer surface, next the air, is comparatively thick and smooth. The lower skin (fig. 4) is formed of cells a little more irregular, and is furnished with mouthlike openings, which are called stomata (meaning in the Greek language a mouth—stoma), and hairs, better shown in the crosscut (fig. 2) of a melon leaf. These stomata present a very characteristic appearance, which is peculiar to the Camellia family. They are surrounded generally by three cells, which are smaller than the others and are flattened. The hairs consist of a single cell shaped like a cone; are generally curved, and have very thick walls. A hair cell is shown in fig. 4, where it is represented as flat upon the leaf; in fig. 2 it is represented standing up. Fig. 1 is the crosscut of the midrib of a tea leaf. Fig. 3 is a stoma of *Sedum lipurium*. (Illustrations compiled from Articles on

[2] Remsen, Inorganic Chemistry, 1892, p. 5. Thaer, in his Principles of Rational Agriculture, speaks of silica, alumina, lime, and magnesia as undoubtedly formed in organized bodies such as vegetables, page 135 of American edition of translation; cf. also Recherches chimiques, p. 242, where Saussure says that to think so is about as silly as to expect to get gold out of a substance in which there is none.

Materia Medica, 1789–1889, by Monsieur E. Collin, inspector-general French army; Botany, by Mr. Balfour, professor and regius keeper of the Botanic Gardens at Edinburgh, and Messrs. Gray and Goodale, professors in Harvard University.)

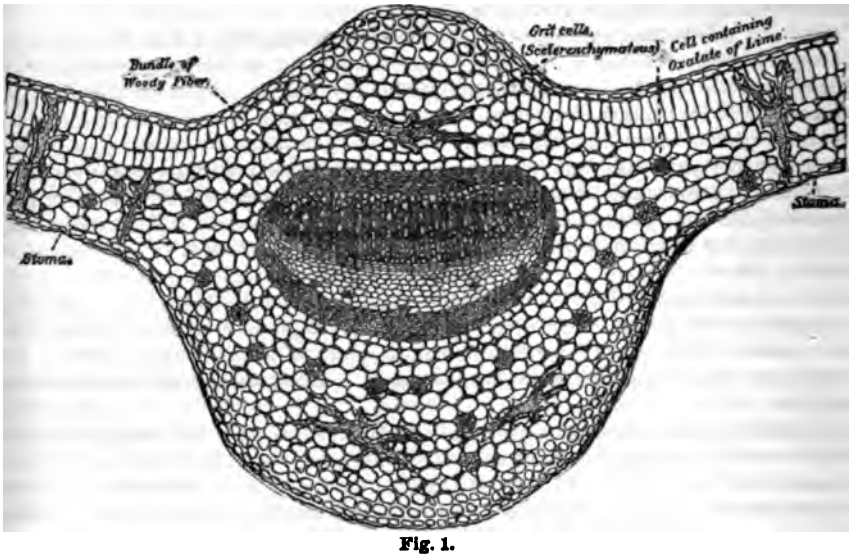

Fig. 1.

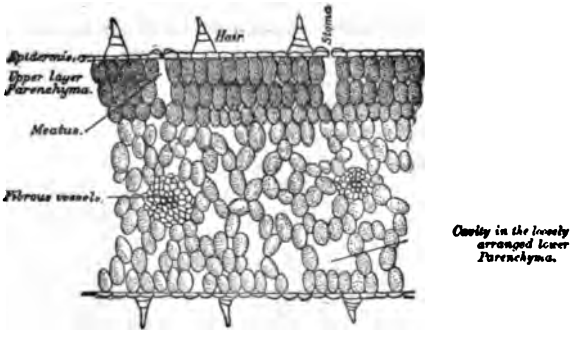

Fig. 2.

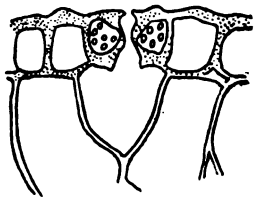

Fig. 3.

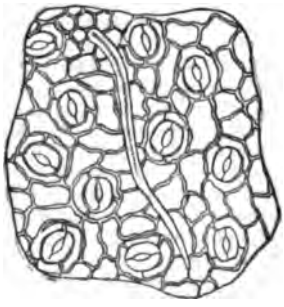

Fig. 4.

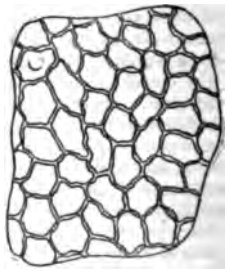

Fig. 5.

The leaf has three exterior exchanges with the atmosphere—one is to discharge water vapor into the air; another to disconnect the carbon of the carbonic acid that it takes from the atmosphere and to hold the carbon and let the oxygen of the

gas acid go, and the third is, in common with all parts of the plant, to respire—to breathe in oxygen and breathe out carbonic acid gas day and night during its entire life. In the light this "transpiration," "assimilation," and "respiration" all go on together. While leaves, stem, and roots are throwing off carbonic acid (as all living things must, and as the skin and lungs relieve the human frame of the waste products of the nervous system), the vital energy of the leaves is expending itself in breaking up in its leaves that very carbonic acid in order to carbonize the juices of the plant, just as the lungs inhale oxygen to burn up the products of that carbonization when they have been introduced into the stomach as food. Conservation of energy of this description excited the astonishment of the British Royal Society over one hundred years ago[1] and was beautifully pictured by Dumas and Boussingault[2] long before the discovery of the physical conception of that fact at Berlin and Manchester.

It would be absurd to contend that the water and carbonic acid breathed out by the plant nourishes that plant, and it seems to follow that the feeding (if such it is) done by the plant through its foliage is confined to the extraction of the carbon suspended in the atmosphere in the form of carbonic acid gas. The simplest experiment imaginable led to this discovery. Finding that confined air was not spoiled by the growth of a mint plant kept in it for some months, Dr. Priestley thought it possible that the process of vegetation might restore the air injured by the fumes from a burning candle. Accordingly on the 17th of August, 1771, he put a plant of mint into air in which a wax candle had burned until it had been entirely consumed, and on the 27th of the same month he found that the oxygen had been restored to the vitiated air, for another candle burned perfectly well in the receptacle in which the air used in the experiment was confined.[3]

But this kind of experiment does not tell all. There yet remains the quantitative proof of the fact. This Saussure gave. Let seven plants of vinca or periwinkle be kept for six days in 2,262 cubic inches of confined atmosphere, of which 7.5 per cent is carbonic acid gas, mixed up with 92.5 parts of common air; then on the seventh day it will be found that 169.6 cubic inches of carbonic acid gas have disappeared and 114.7 cubic inches of oxygen have taken its place.[4] Fifty years afterwards such an experiment in the hands of Boussingault would have resulted in giving a volume of oxygen practically equal to that of the dissipated carbonic acid.[5] It is quite safe, then, to say that the leaf eats (so to speak) of carbon, and that indirectly it takes this from the air, though it must never be forgotten that the capital function of the leaf is, to use an expression necessitated by our ignorance, "to elaborate" the sap.[6] Why the leaf should act thus through a green substance it contains called chlorophyll has engaged the attention of many, but there is something about the question that stunts the growth of an hypothesis.

If the carbon that is required by vegetation is obtained from the atmosphere, which contains only three parts of carbonic acid in every 10,000 parts of common air, it might be supposed that nitrogen, which forms 8,000 parts of every 10,000 of the air, would also be obtained in the same way. But nature in feeding vegetation prefers to decompose compounds, and during this century, at least, it has become more and more the ambition of agricultural chemists to discover the source of nitrogen obtained by the plant. Not that nitrogen is more important than free oxygen or water in vegetable nutrition, but because it was recognized that it

is the very essential ingredient of fertility that man must supply. In the valle of the Nile nature unaided annually performs a great irrigating and fertilizin feat,[1] but in countries where human labor and foresight have to overcome natur deficiencies farm-yard manure or, in general, the waste products of life wer long thought to be alone capable of supplying the missing ingredient. Even no in China, the most fertile country, it is said, imaginable, after centuries of cult vation the people still continue to use this simple, antiquated method of preser ing the fertility of their soil. Europe is more advanced, and were text-books c agriculture and papers read before learned societies to be consulted as a guide i would appear that the farmer who asserts the preeminent value of farm-yar manure is worthy of the reply made by one of Molière's physicians to a patien who contended that the heart was on the left side of the human body, "Oh, w have changed all that now." Manure, said Liebig, is extremely useful to th plant when it has no leaves, since it furnishes to the roots the carbonic aci required in starting the new growth in spring, but as for its being the main sourc

Cross-section of roots.—A: Showing simple form of central portion, in which there are tw bundles of fibers (F) and two bundles of vessels (V). B: Root of bean, showing more compl cated structure, as there are four central bundles of fibers (F), and four of vessels (V.) (Afte Van Teighem.)

of nitrogen. that is not so, for the plant obtains that gas from the ammonia of th air which is washed into the soil by the rains.[2] To this M. Boussingault[3] imper sonally replied that the experience of all farmers is of far more value than th opinion of one scientist.

Theory and practice and the doctors thus disagreeing, it may be well to inquire "What is a root?" or rather "What is the function of a root?"

What the mixture of gases called the atmosphere is to the leaf, that and mor is water to the roots. We are not more surprised to learn that the air we breath can be solidified than to learn that by irrigation a desert may be made fertile. I is true that some forms of vegetation, such as mosses and mushrooms, have n roots, but the conditions of their growth recalls a charming fancy of Voigt wherein he claims that vegetable mold is not wholly dead matter, but is a vas

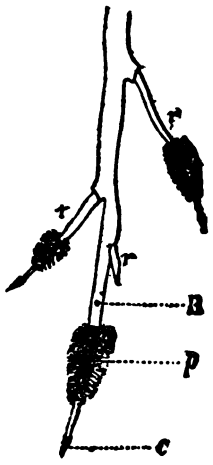
[2] Organic Chemistry, Liebig pp. 59, 47, 118, 69, 72-3, second American edition (Webster, editor)

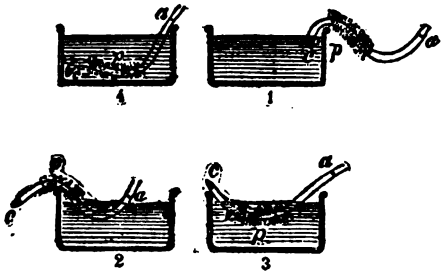
[3] The statement is made on the authority of Professor Deherain, his friend.

pervading, unorganized plant which bears and nourishes other plants as a tree affords nutrition to all its branches and shoots.[1]

The root is then an apparatus to absorb water. It is composed of three parts, a cap or penetrating point, a muff of fine hairs which follows close behind the cap, and finally an arm or the body proper of the root, which is at once an anchor, an alimentary canal, and a pump. For the direct purpose of plant nourishment the most important of these parts of the root is the muff of absorbing hairs. It is this structure that takes up nutriment suspended in the moisture of the soil, as is shown by the following illustrated statements:



Diagramatic illustration of root: *r*, root; *p*, muff; *c*, cap.



1. Both root cap and muff submerged in fertile liquid. 2. Root cap alone submerged. 3. Neither cap nor muff submerged. 4. Muff alone submerged. In 1 and 4 plant lives, but in 2 and 3 it dies. "It is well to cover surface of liquid with oil in making this experiment."

The following are Saussure's rules regarding absorption of solid substances by the roots:[2]

1. The roots of plants take up alkali salts and humus extract in a smaller proportion than they are held by the water in which they are dissolved.

2. The pruning of the roots, their decay, and, in general, the pining away of the plant favor the absorption of salts and humus extract.

3. A plant does not take in in equal proportion all the dissolved substances held by the water surrounding its roots. In general, it takes in least of those substances which are the most viscid.

4. If the weight of the extracts which the most fertile soil affords be compared with the weight of the dry plant which has grown upon it, it will be found that the plant has obtained only a small part of its weight from that soil.

Such is the root, the apparatus which is supposed to obtain the nitrogen required by the plant; but though the best established facts in agriculture had long before concurred in showing that nitrogen is fixed by growing plants, it was not until 1838 that an attack in the Saussurean manner was made upon the problem by Mr. Boussingault, a traveler, a chemist, and a farmer. "Had I chosen the old line of investigation," said this experimenter, "I would have failed; so I sought an answer by aid of an elemental analysis of the seed sown and the crop of seeds a similar seed produced from water and air."[3] The results thus obtained are fundamental, and are summarized by the investigator in this language:

1. Clover and peas grown in a soil absolutely without manure acquire a very

[1] Quoted approvingly by Thaer in his Practical Principles of Agriculture. American edition, p. 167 (1840).

[2] Recherches chimiques, p. 270-271.

[3] Rural Economy, p. 43.

appreciable quantity of nitrogen in addition to a large quantity of carbon, hydrogen, and oxygen.

2. Wheat and oats grown under precisely the same circumstances took carbon, hydrogen, and oxygen from the air and water around them, but no nitrogen.[1]

As it is known that plants absorb water—that is to say, oxygen and hydrogen—and it has been shown how they absorb carbon from the carbonic acid of the air, the question arises, where did the peas and clover of those experiments get the nitrogen that was beyond the power of the wheat and oats to procure? Do leguminous plants make their own nitrogen? Probably Mr. Boussingault would have considered the last question too trivial for an answer. At all events, he neither asked the question nor attempted to explain whence came the nitrogen produced in his remarkable tests. Upon that point, in 1838 at least, he "could only offer conjectures," and yet would not.[2]

Nevertheless, a genius of a more didactic than an experimental cast, and one having no doubts about anything in his specialty, did not hesitate to explain the phenomenon. "The first and most important question to be solved," said Professor Liebig, "is how and in what form does nature furnish nitrogen to vegetable albumen, and gluten to fruits and seeds. This question," he says, "is susceptible of a very simple solution." His solution was this: There is not the slightest reason for believing that the leaves or the roots of plants take in nitrogen directly from the atmosphere for the purpose of feeding the plant, but there are numerous facts showing that the roots of plants do take up a compound of nitrogen called ammonia given off into the air by the putrefaction of animal matter and thence washed down into the soil by the rains.[3]

It must be confessed that the hypothesis was built upon strong grounds of probability. From Saussure down it had been known that there is a trace of ammonia in the air,[4] and the ease with which water absorbs the gas (well known as the "ammonia" of the shops), the acknowledged power of the plant to break up both carbonic acid and water into carbon, oxygen, and hydrogen, and the excess of hydrogen which is found in the plant,[5] all seem to supply every evidence required by conjecture to enable it to resolutely affirm that ammonia gas from the atmosphere is the source of vegetable nitrogen. But while Liebig was declaiming on the theme that humus is merely "a slow and constant source of carbonic acid to the roots," and that to spread manure upon the fields, which already contain more nitrogen than the manure spread upon them contains, for the purpose of adding nitrogen to those fields, is folly,[6] Boussingault was asserting that "whatever may be the constitution and physical properties of land, it yields lucrative crops only in proportion as it contains an adequate quantity of organic matter, in a more or less advanced state of decomposition, called humus, or what is nearly the same thing—vegetable earth or mold.[7] Having thus apparently flatly contradicted Baron Liebig, he goes on to say that no working of the field, nor favoritism of climate, nor salts or alkalis will take the place of

[1] It is impossible here and perhaps unnecessary to follow up Boussingault's work in attempting to solve the nitrogen problem. In a positive way he never got further than his 1838 declaration.

[2] My mode of experimenting had in view merely to determine the assimilation of nitrogen by certain vegetables without entering into the question of the means by which this was effected. Upon that point I could only offer conjectures.

[3] Organic Chemistry, pp. 9, 10, 69, 72, second American edition, Cambridge, 1841. The key to Liebig's position is this: Humus is decayed vegetation, therefore vegetation must have preceded humus. But there is a difference between a lichen growing on an undisintegrated rock in "symbiosis" with a microbe and a wheat plant growing in soil or as it is called disintegrated rock.

[4] Recherches chimiques, p. 207, footnote.

[5] Nutrition of Plants, Deherain in Dictionnaire d'Agriculture.

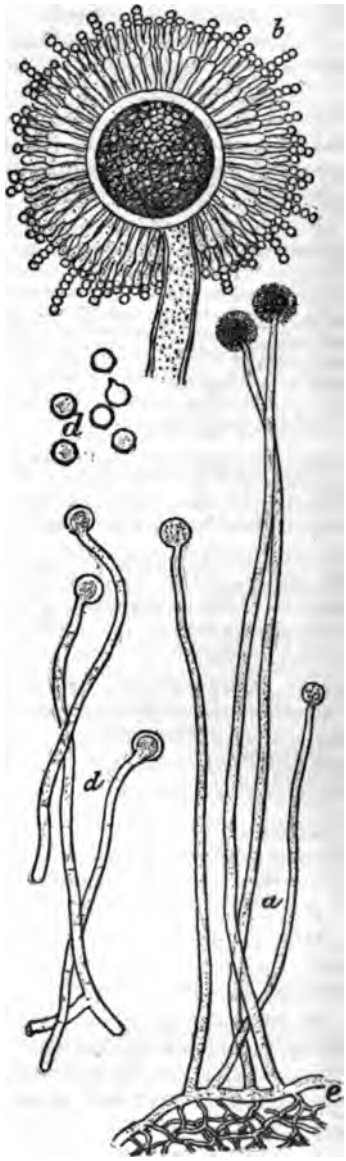
[6] Organic Chemistry, pp. 90, 59, 47, 118, and perhaps 112.

[7] Rural Economy, Chapter V, On manures, p. 309, second English edition.

manure, which conclusion so exercised Mr. Georges Ville that he was lead up to publishing a "School of Manures," in which the "student" is told by the "professor" that it is not necessary to manure a clover field with farmyard manure for the purpose of nitrogenating it, as clover gets all its nitrogen from the air, and the phosphate, potash, and lime it requires may be best put on as mineral matter, "for manure only acts by the nitrogen, phosphate, potash, and lime it contains."[1]

Perhaps the situation in 1850 had not changed very much from that of 1804, when Saussure wrote, "If nitrogen is a simple body, if it is not a part of water, it must be conceded that plants assimilate it only in the form of vegetable and animal extracts (humus), in ammonia vapor, or in other compounds dissolved in water, which they can take from soil or air; for it must be admitted that when a plant grows in a confined atmosphere by the help of a little distilled water, the new growth gains nitrogen at the expense of the parts that had been formed before the experiment commenced."[2] At all events, when Pasteur, in 1862, said that the entire study of nitrification would have to be all done over again, no one thought his criticism ill timed. But before exposing the developments made by the new line of investigation, it is desirable to show the structure and function of an organism which M. Pasteur found in a wine tub, Mr. Tyndall even in the pure air of the Alps, and M. Schloesing and others, more wonderful still, found in the ground—the ubiquitous microbe in all its bewildering uncertainty of an administering and a destroying angel.

For the present purpose microbes may be divided into two classes, one of which, in the air or in oxygen, will manifest its properties as a ferment, while the other will only work in a vacuum or in an atmosphere of carbonic acid or hydrogen gas. Both sets require oxygen, but the set that works in a vacuum, etc., has the ability to break up compounds containing oxygen in order to obtain that absolutely necessary element of life, hence it is called an anaerobe, while the microbes, that work in an oxygenated atmosphere like common air, are called aerobes. The dreadful scourge of hospital amputations, known as septicemia or blood poisoning, is caused by an anaerobe, which finds a breeding place in the carbonic-acid gas surrounding a small piece of dead flesh or a clot



Aspergillus niger. (*a*) General appearance, magnified 30 times. (*b*) Flower magnified 200 times. (*c*) Mycelium ramifying in nutritive fluid. (*d*) Spores magnified 500 times. (After Raulin.)

[1] The Chemical School of Manures, Philadelphia translation.
[2] Recherches chimiques, p. 207.

of blood, and the carbonic-acid gas and marsh gas produced at the bottom of a manure pile are due to the same cause. On this occasion an aerobe, the *Aspergillus niger*, is chosen for illustration for reasons that will suggest themselves as its performances are related.

This aspergillus (aspergillus, a brush, and niger, black) lifts its black tuft of spores above the mycelium or network which ramifies in the liquid that nourishes it. From this mycelium little cylindrical columns somewhat larger than the threads of the mycelium run up into the air, terminating in heads formed after the manner of a dandelion ball or tuft when the yellow flower has fallen, except that the many projecting bodies of the aspergillus are black instead of white and carry balls or "spores" at their extremities instead of gossamer stars.

Now, suppose one or more of these balls or spores should be sown in a liquid at blood heat, made up of ingredients such as these:[1]

	Grams.		Grams.
Water	1,500	Carbonate of magnesia	.40
Candied sugar	70	Sulphate of ammonia	.25
Tartaric acid	4	Sulphate of zinc	.07
Nitrate of ammonia	4	Sulphate of iron	.07
Phosphate of ammonia	.60	Silicate of potash	.07
Carbonate of potash	.60		

Then certain precautions of a technical nature necessary for the experimenter, but not for the reader, to know being taken, there will appear in eighteen or twenty-four hours a mycelium (c of the cut) at first white, but after the lapse of another day yellow and then brownish, and finally black because of the deposit of spores. Now, what is the influence of the potash, for instance, upon the growth of the aspergillus? The answer is found in this way: Take two receptacles, one containing the liquid given above and the other the liquid minus the potash. The whole liquid will produce 25 grams of dried plant or fungus; the liquid, without potash, will produce only 1 gram. The suppression of the potash has caused the product (dried) of the aspergillus to fall twenty-four times. Let us then say that its usefulness is measured by the number 25, and in the same way (growing two crops so as to exhaust the liquid and measuring both crops) it is found that the value of—

Ammonia is	153	Oxide of zinc is	10
Phosphoric acid is	182	Oxide of iron is	2.7
Magnesia is	91	Silica is	1.4
Potash is	25		

The numbers opposite ammonia, phosphoric acid, potash, and magnesia need not astonish us, says M. Du Claux, chief of the Pasteur Institute, they having long been known to be excellent manures.

Microbes acting thus are called ferments: that is, they break up a chemical compound in which they start to grow into elements which are left free to rearrange themselves, it may be assumed, in new combinations. In such a way wine is turned into vinegar and animal bodies into dust. After having been used to explain the diseases of men, beasts, silkworms, beer, milk, and cheese, the microbe is now offered as an explanation of fertility. The discovery of this function of the microbe is due to two French chemists, Messrs. Schloesing and Müntz, who have so candidly described the beautiful experiment which acquainted them with the fact that their joint "note" to the French Academy of Sciences (in 1877)[2] is given nearly in full.

[1] Following M. Jules Raulin—Recherches sur le développement d'une mucédinae dans un mille artificiel, 1870.

[2] Comptes Rendus. Tome 84, p. 301; Sur la nitrification par les ferments organisés.

Note to the French Academy of Sciences, by Messrs. Th. Schloesing and A. Müntz, concerning nitrification of the soil by organic ferments.[1]

It is generally admitted that the nitrates which are formed in the soil come from the burning (chemically) of ammonia and nitrogenous matter of organic origin, but there is no agreement upon the mechanism by which this burning is done. Is the nitrification a result of direct reaction, purely chemical, between oxygen gas and nitrogen compounds; is it brought about by the intermediation of organisms acting as ferments; or, indeed, is it produced by both of these actions working in concert? These questions have been asked since the day when M. Pasteur showed that certain organisms—such as the so-called "mycoderma" of wine and vinegar—have the property of introducing the oxygen of the air into organized substances of the most miscellaneous kinds, and also that they are the most active agents in the destruction of organized or, so to speak, biological matter which has lost its vitality. Now, M. Pasteur has also shown that organic substances (which are, at least, as alterable as those which may be supposed to nitrify in the soil) oppose a singular resistance to oxygen when they are protected from all contact with germs of a fermenting organism. In putting these two facts together we are led to suppose that living agents must intervene to effect combustion in the soil, at least in the case of rapid combustion and nitrification, without our being obliged for all that to refuse to free oxygen, working in virtue of chemical forces, the faculty of burning and of nitrifying nitrogenous matters. In short, we assume a living as well as an inert chemical agent in the destruction of dead organic matter.

Convinced of the truth of these conceptions, M. Pasteur since 1862 has constantly asserted that the study of nitrification must be made ever from the point of view of the function in nature of the microbe. The experiment we are about to report confirms the anticipations of M. Pasteur without just now rigorously maintaining their truth.

One of us [Müntz] while occupied recently with an investigation concerning the irrigation of land with sewage water desired to ascertain whether the presence of humic matter in a soil is indispensable to effect the purification of water of that kind. In short, is humus necessary to cause the total burning up of all impurities held in solution by sewage water? To this end, a large glass tube 40 inches long was filled with 11 pounds of quartz sand, which had been purified of all organic matter by being exposed to a red heat and then mixed with 100 metric grams of carbonate of lime in powder. The sand was watered every day with the same quantity of sewage water, put on in such a manner that the liquid took eight days to descend through the tube. During the first twenty days no appearance of nitrification was produced, and the proportion of the ammonia in the water filtered in this way remained invariable. On the twenty-first day the niter appeared and increased very rapidly, and then it was evident that the sewage water on leaving the apparatus contained no trace of ammonia.

Let us assume that in the fact above related the oxygen and nitrogenated matter had been burned chemically by the oxygen working directly on the organic matter held by the water, that is, burned it like nitric acid will burn a copper plate, or oxygen will rust (i. e., burn) a nail in a moist atmosphere. In that case the question might be asked why the burning had waited twenty days before it began. That delay is better accounted for upon the hypothesis that it was caused by a living ferment which is not able to work, evidently, unless, after their germs have been sowed, they have had time to develop.

The experiment commenced in June and had continued four months, when it occurred to us to introduce into the apparatus the vapor of chloroform. One of us [Müntz] had shown that this substance suspends all activity among living ferments without in any manner interfering (entraver) with soluble ferments. If, then, the nitrification observed in our apparatus after the twentieth day was produced by organic beings, chloroform ought to stop it by putting those organisms to sleep. If, on the contrary, the nitrification was a mere chemical reaction, the chloroform would have no effect in stopping nitrification, which would go on as before. Accordingly we placed upon our sand in the tube a little vase full of chloroform and diffused its vapor through the tube by a current of forced air. As we have said, it took eight days for the daily dose of sewage waters to run through the sand. Thus we were unable to note the immediate effect, but after ten days the liquid running through contained no trace of niter; on the contrary, the ammonia of the water was again found in its complete totality. The filtered

[1] Comptes Rendus, tome 84, p. 301.

or to take out afterwards all the oxygen which is produced by the breaking up of the carbonic acid by the chlorophyll, it is necessary to provide for furnishing the carbonic acid as it is wanted and then to withdraw the oxygen set free by the leaves as the experiment proceeds.

In a kind of elongated cylinder of glass we introduced sand, out of which all organic matter had been first burned and then saturated with a mineral solution free from nitrogen, in which the plant will grow. Every precaution is taken to keep germs from the air out of the apparatus. In the sand are sowed three seeds of dwarf pease (pois Gouthier), and these are watered with a little pure water in which there has been placed some fresh nitrogen nodes ground up in a mortar (broyé),[1] taken from pease and beans that have grown in the open air. The cylinder is then placed in a south window. The seeds sprout, and we continue our experiment for three months, August to October, two trials being made.

The pease did not grow very large, but they were healthy and, for their size, vigorous. They flowered, but did not fruit. The figures are these:

Direct method.[1]

	First experiment.	Second experiment.
Nitrogen gas introduced at beginning.....cu. centimeters..	2681.2	2483.3
Nitrogen gas found at close of experiment..cu. centimeters..	2652.1	2457.4
Difference or nitrogen fixed	29.1=36.5 mg.	25.9=32.5 mg.

[1] One seed failed. A centimeter is near 0.4 inch; a cubic centimeter is therefore about .061 cubic inch. The milligram is $\frac{15.6}{1000}$ grains.

It is impossible to attribute these differences to errors which were caused by the method pursued. Suppose that in each measurement the maximum error was committed, and counting all the errors in such a sense that they would produce the greatest possible error in the total, yet this would not exceed 3 cubic centimeters.

An examination of the plants at the end of the experiment brought out the fact that there were a large number of nodes upon their roots.

Applying the method of Hellriegel and Wilfarth we get by the—

Indirect method.

	First experiment.	Second experiment.	Peas grown without "nodes."
Nitrogen in the soil before the experiment, in milligrams.....	4.3	4.3	4.3
Nitrogen in the pea seeds, in milligrams	28.3 } 32.6	28.2 } 32.5	28.2 } 32.5
Nitrogen in the soil at the close of the experiment, in milligrams.....	15.1	17.5	8.3
Nitrogen in the plant, seeds and all, in milligrams.....	58.1 } 73.2	49.1 } 66.6	24.8 } 33.1
Gain of nitrogen, in milligrams	40.6	34.1	.6

To sum up: The indirect method shows that there was a gain of nitrogen during the course of growth, while the direct method shows that this gain is really due to the fixation of nitrogen gas, for when the apparatus had been all connected together a perfect vacuum was created in all its parts, and then this vacuum was filled with, first, pure oxygen, 20 to 25 parts; pure carbonic-acid gas, 6 to 9 parts, and pure nitrogen, 65 to 70 parts, the last being measured with the greatest possible exactitude by means of a volumeter.

When this "note" had been read to the academy, M. Berthelot observed: "This note seems to me to close the polemic relative to the fixation of free nitrogen by the concurrence of the soil and the plant. It shows, indeed, in confirmation of a

[1] The microbe of these nodes has been classed among the myxomyceles, bacterias, and filamented mushrooms. While some botanists refuse them "all autonomy," Laurent thinks they should be classed between the last two, and might be called Pasteuriaces. They must come from a germ or from land carrying microbes.

long series of my observations since 1883 and confirmed by Messrs. Deherain, Frank, and Tacke, together with the observations made by Hellriegel and Wilfarth, Brèal, and Prozmowski, that the soil and plants enrich themselves with nitrogen by the influence of microbes, microbes of which I discovered the presence in the soil and of which the German savants have discovered the parasitism and specific action upon the roots of the leguminosæ."

As beautiful and as important as was the experiment with chloroform by Professors Schloesing, sr., and Müntz, it is possible to think that it did not surpass in the latter particular still another experiment of Schloesing, jr., and Laurent in 1891. They made two tests. In the first they found that nonleguminous plants absorbed nitrogen just as in the year before by the same method they had proved that fact of the leguminous plants. This surprising result was not credited, however, for certain mosses (Brynum, Leptobrynum, rootless plants) and algæ (conferva, oscellaria, nitzschia, likewise rootless) and other like green plants of "low orders" were seen little by little to cover the soil. A second series of experimentation was undertaken in which the green plants of the lower orders were smothered out by a thin layer of calcined quartz sand. After that no plant except those of the leguminous order was found to fix nitrogen. From these tests they drew two conclusions: (1) There are green plants of a low order botanically, which take nitrogen from the air, and (2) nonleguminous plants do not fix nitrogen in a measurable quantity, while under the same conditions a legumin will.

But despite the present accentuation of nitrogen as a food of plants taken in through the roots, as nitric acid (?), it has not always held its present position. Saussure wrote in 1804: "I have found the phosphate of lime in the ashes of every plant I have examined, and there is no reason to suppose that plants can exist without it."[1] Liebig speaks more openly: "Ashes of plants represent the whole nourishment which vegetables receive from the soil. By furnishing them in sufficient quantities to our meadows we give to the plants growing in them the power of condensing and absorbing carbon and nitrogen by their surface. With a knowledge of the exact quantity of ashes the farmer will be able to keep an exact record of the produce of his fields in harvest, like the account book of a well-regulated manufactory, and then by a simple calculation he can determine precisely the substances he must supply to each field, and the quantity of these in order to restore their fertility." Well might Boussingault, a scientist, say that the experience of many farmers was worth more than the opinion of one scientist. He, indeed, acknowledges that artificial fertilizers, including, of course, nitrate of potash, are "mineral manures or stimulants," but remarks that, "Ashes, gypsum, or lime spread upon the soil would not improve it in any sensible degree;" and, having thus seemingly contradicted Liebig, goes on to partially acknowledge the justice of Liebig's pretension that nitrogen is unnecessary by saying that nitrogenous stuff alone (such as nitric acid) would be no better than the alkalis or phosphates or limes. What is necessary is a combination of the two, one the nitrogen coming definitely from the air (certainly Liebig's contention), the other from the "solid parts of the globe"[2] (which "other" Liebig wanted put on when not present in the parts of a portion of the globe to be manured). Comparing these statements with the experiments of Messrs. Schloesing, jr., and Laurent, it will be found that if the microbe be called manure both Liebig and Boussingault are right, at least as far as the leguminous plants are concerned, though both were quite ignorant of the facts in the case. What, then, do plants get out of the soil? And we are recalled to Saussure's work.

It was believed by many before Saussure that plants elaborated for themselves the ashes left when they were consumed by fire. It seemed so natural to think so

[1] It is found in the sap of the maple tree used for making maple sugar, for instance.
[2] Rural Economy, p. 311.

that no one took the trouble to show that it was so.[1] Some had found that the green parts of trees and plants give more ash than twigs and the twigs more than the limbs or trunk, others that annual plants transpire water more freely than a tree, but it remained for Saussure to make the analyses that were used for more than half a century.

Let us take two of Saussure's analyses of ashes:[2]

	Ripe wheat.		Ripe corn (Zea-mais).	
	Straw.	Seed.	Seed.	Straw.
Potash	12.5	15	14	59
Phosphate of potash	5	32	47.50	9.7
Chloride of potash	3	0.16	0.25	2.5
Sulphate of potash	2	Trace.	0.25	1.25
Phosphates ("earthy")	6.2	44.5	36	5
Carbonates ("earthy")	1	0	0	1
Silica	61.5	0.5	1	18
Oxide of iron	1	0.25	0.12	0.5
Lost	7.8	7.59	0.88	3.5
	100	100	100	100

It is very evident where the phosphates are needed in an agricultural seed plant. But in order to show how small a part all the ash constituents of a seed are of the unburned seed the following analysis is taken from Boussingault[3] to supplement those of Saussure given above:[4]

Contents.	Wheat seed.	
	Before germination.	After germination.
Carbon	45.5	41.1
Hydrogen	5.7	6
Nitrogen	3.4	*a* 8
Oxygen	43.1	39.5
Ashes	2.3	*b* 5.4
	100	100

a Supposed. *b* Calculated.

It has thus been shown that two gases of the atmosphere, carbonic acid and nitrogen, are used by nature in building up that part of the plant structure which, when wood is treated by fire in a certain way we call charcoal, but cellular structure when the plant is merely dried by a heat that evaporates the uncombined or chemically loose water which it holds mechanically in its framework. It is supposed, probably proved, that the carbonic acid broken up by the leaf is the source of its cellulose, and that its nitrogenous matter is elaborated by the same agency. No space has been devoted to proving that plants absorb water, nor has any notice been taken of the fact that water is thought to be decomposed into its elements, hydrogen and oxygen, by the plant. If such decomposition does occur it occurs within the plant, though the formation of the carbohydrates (cellulose,

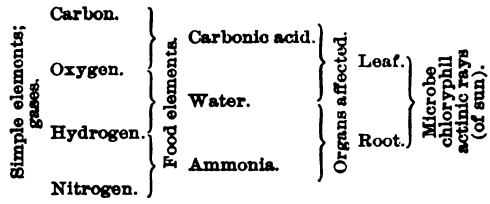
[1] Thaer (Principles of Agl., section 3, Agronomy, p. 135 of American edition, 1846) says that silica, alumina, lime, and magnesia "are formed in organized bodies."

[2] Recherches Chimiques, tables to chapter 9.

[3] Rural Economy, p. 26, English edition.

[4] Liebig classified cultivated plants into potash plants, lime plants, and silica plants, according to the presence of those substances in the ash of the straw. Potash plants are corn, the beet, turnip, etc.; lime plants are peas and clover; and silica plants are those from which the staff of life is obtained—wheat, rye, oats, and barley.

starch, etc.) may possibly be formed without the decomposition of water. Whatever authority deems true on this point will be given when treating of the self-activity of plants. But there can be no doubt that the ashes represent the contribution of the soil to the plant, and that the matter so furnished is, in the form of silica, decidedly present in the straw and, in the form of phosphorus, equally present in the seed. On the other hand, it is to nitrogen that the philosophers of vegetation of the last half of the nineteenth century would attribute the characteristic of vigor, and, indeed, the value of ammonia and of phosphoric acid in the Aspergillus experiment seems not unconnected with its heavy crop of spores and the heavy growth that produced them. Therefore by leaving out of consideration the ash elements we may make a diagram somewhat as follows:



THE AGRICULTURAL PROCESS.

In the foregoing we have been dealing with hypotheses founded on experiments conducted according to the canons of induction.[1] An experiment or series of similar experiments furnished a new truth or a proof of a speculative conception, and this the syllogism classified and converted into a theory that was true as far as the whole meaning attached to the words were not contradicted by other facts not yet recognized as connected with the question or as yet unknown. The discovery of a truth in this way is almost always brought about by human interference and, if the statement be not held too rigidly to the exact meaning of its terms, it may be said that the method disregards time and place. But there is another method of discovering truth in nature, which Mr. Mill in his logic calls a "collocation of facts," which is illustrated by Kepler's discovery of the mathematical figure made by the planets in their passage around the sun.[2] Time and place in an investigation such as this, requiring the collocation of an immense number of observations of other astronomers through a long course of years, are the very elements of a discovery or the making of a scientific generalization.

An investigation on the collocation of facts system has been going on at Rothamsted for over fifty years. Nature is not interrogated in a flower pot at that establishment, and the results of a uniform treatment of the fields under observation has been purified by the variations of a continuous number of seasons. It is an agricultural experiment station where nature is besieged, not attacked sword in hand. The inquiries at Rothamsted may be said to include two great problems: The one relating to the effect of variations in soil conditions under fluctuating atmospheric conditions on the crops; the other being the reciprocal problem as to the effect of crops upon the soil.

It may be of service here to ask "What is a soil?" It is said that it is disintegrated rock, and thus the question becomes an investigation of the conditions which cause disintegrated rock to grow the plants which undisintegrated rock refuses to nourish and of the source of rock. To follow the last out would require us to follow the earth—a satellite of the sun like the moon is of the earth, itself—back to the time when it was being disengaged from the sun[3] as Saturn is now to

[1] A system of Logic, Ratiocinative, and Inductive, by John Stuart Mill, Book III.

[2] Kepler's habit was to rummage through the observations of his predecessors, look at them, in all their lights, and then distill from them the laws which united them. (Tyndall: Six Lectures on Light.)

[3] La Place's Nebular Hypothesis.

be seen disengaging "rings," and when the earth as an original part of the sun was possibly a blazing mass of hydrogen.[1] Nor would such an excursion be satisfactory, for it would be necessary to look upon the rocks as the slag or sediment of the terrific combustion or a cold form of hydrogen gas which is given off when most metals are heated.[2] This, therefore, will suffice that the rocks, particle by particle, are being carried away toward the sea by water which is a compound of hydrogen. Yet the action of water, either in its liquid or glacial state, in grinding down the rocks so as to catch and hold fertility, is not agriculturally speaking of so much interest as its offices in effecting the formation of decayed vegetable matter or humus, which certainly is not a cooled rock. This organic soil is the product of water vapor which originally fed the primitive plants of which the algæ and the lichens, though air-fed plants are, comparatively speaking, highly evolved forms.

From the decay of such forms has arisen the vegetable soil of the globe or humus, which changed under mechanical pressure by heat and exclusion from air, is burnt beneath the boilers of our steam engines in the form of coal, and when reconverted into vegetation is consumed in the animal body. How soon this vegetation appeared after the earth had lost its heat can not be said; but it is not too much to say that it awaited the first clouds, if not the actual fall of rain.[3] How it began or whether nature is even now calling from unorganized matter new forms of life is a question that must be left to those who believe in the creation of an unique parental cell and slow process of natural selection or "evolution," and their opponents, who uphold "spontaneous generation."

There are but few facts in the history of the earth's surface that are not easily matters of unlimited controversy. Even of the Tertiary-Quaternary period which immediately preceded our own we only know that nature seems to have specialized her backboned creatures from the extraordinary beasts—half giraffe and half alligator, the restorations of which people our museums—to a wholly land animal, and changed an as yet unknown climate to one of intermittent periods of ice

[1] Mr. Lockyer's Meteoric Hypothesis. In a letter in French published by the French Academy of Sciences this astronomer put his earlier theory in these simple sentences. The hotter a star is the simpler is its spectrum [fewer kinds of stuffs it has in it] and the metalliferous elements appear in the order of their weight, taking hydrogen as 1. So we have (1) very brilliant stars in which are only to be seen hydrogen in enormous quantities and magnesium, (2) cooler stars as our sun in which we find hydrogen + magnesium + sodium, or instead of sodium, calcium, iron, etc., but no metalloids [oxygen, nitrogen, carbon, phosphorus, and in fact he might have said and did almost say so in the original letter, the minerals of the vegetable kingdom], (3) cooler stars still in which all the metal elements are associated and their lines are no longer visible in the spectrum, but where we find the spectrum of the metalloids and the compounds [such as on the earth?]. Finally the older a star becomes the less there is seen of free hydrogen, and on our globe we find no free hydrogen (p. 344, of the Meteoric Hypothesis). It would appear that Mr. Lockyer's present view is that a swarm of meteors coming together increase in heat until they become a brilliant star like Sirius, and then having reached their limit of gaseous condensation and being, therefore, at their hottest begin to solidify. See Note A, to this chapter.

[2] In Professor Ramsay's address as president of chemistry section, British Association for Advancement of Science (Toronto, reported in Nature, August 19, 1897), he says: "Most minerals give off gas when heated, and the gas contains as a rule a considerable amount of hydrogen."

[3] "As soon as the central heat ceased to act upon the temperature of the surface of the globe and of the atmosphere, the precipitation of vapors must have become almost general * * * and from the first drop of water which fell upon the still burning surface of the earth to the first ray of sunlight which shone upon the ocean is the period when the geologist must look for the plutonic forces upon the crust of the globe." (Revolutions of the Crust of the Earth, by Professor Pilar, University of Brussels.) Mr. T. Sterry Hunt, in a statement prepared at Professor Henry's request, which is published as "On the Chemistry of the Earth," says: "The part which vegetation has played in the chemical history of the globe has not been limited to purifying the air of carbonic acid. It seems to have been the great agent through which so large a force has effected a partial decomposition of the thoroughly burned or oxidized materials of the primitive world. By means of growing plants carbonic acid and water are reduced, giving rise to the various forms of carbon and to hydrocarbonaceous bodies, which act upon the sulphates deoxidizing them."

sheets "a mile or two thick." There are, however, a few facts furnished by geologic changes of an organic nature now in course of consummation that will serve to give, no matter how faintly, a conception, based on recorded experience, of the difference between the inorganic and the organic substances which form the aerated surface of the globe.

To those who for pleasure or health have visited Florida, especially the region of the chain of lakes whose waters, known as the Kissimmee River, first collect in Lake Tohopekaliga and ooze out from Okeechobee into the ocean, it is useless to explain that the country is flat and that the geological soil or "disintegrated rock" is sand. To those who have watched in that region the matter floated out of a descending pipe on its way to tap artesian water and to those who have tasted that water when found, it would be equally useless to say that the region is lifted above the Atlantic by a pedestal which, partly, at least, has been constructed by a coral-making animal.[1] To them it will not be difficult to show that the portion of the Floridian peninsula which is bounded on the west by the sluggish waters of the St. Johns and the Kissimmee, and on the east by the Gulf Stream, is a product of a sea change.

When the waters of the caldron-like Gulf receive the mechanical impress that shoots them through the narrow neck of sea that separates Cuba from Florida, the rapid current eddies in the open Atlantic, and so far as it does so deposits the suspended matters its waters have gathered up from the sediments of the Orinoco, the Mississippi, and the mountain torrents of the eastern slopes of the cordilleras of Spanish North America.[2] Thus the ocean stream, keeping its channel clear by the force of its own momentum, makes a delta for itself in the ocean as the Mississippi makes its "passes" in the Gulf.

Observe the cross section, fig. 3. At the right we have the Gulf Stream sweeping along in its 400 or 500 fathoms groove between precipitous banks of 2 or 3 fathoms below the surface on the Bahama Island side and of 30 or 40 fathoms on the Florida side, and rapidly shoaling as it approaches the Floridian keys. Here is the opportunity of the coral-making animal. Nourished by a warm, swift food-bearing current, the coral animal can excel the builders of the Egyptian pyramids. To aid the imagination the mound marked "Coral reef" may be taken as a beginning of a process which has resulted in the formation of Everglades and the Atlantic side of Florida, and then let the steps be given in the words of Professor LeConte:[3]

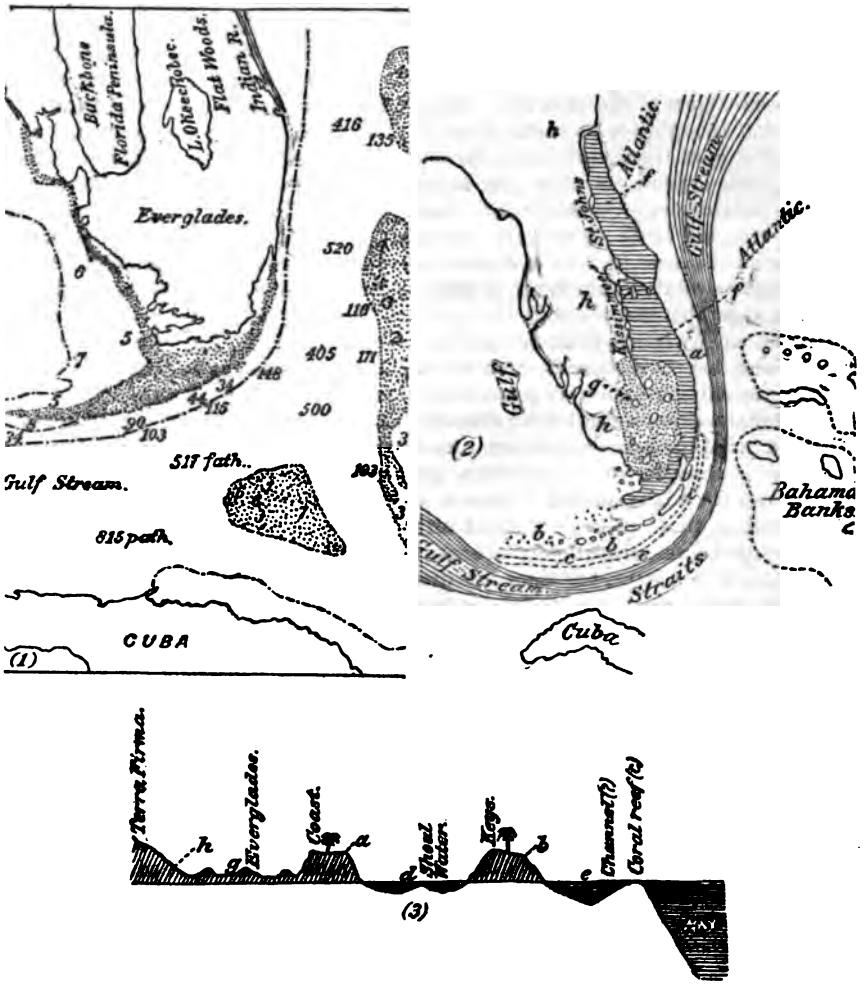
On the living reef islands have just commenced to form. Some are yet only a collection of large coral fragments, the nucleus of an island. Some are more compacted by smaller fragments thrown in among the larger. Some are small, but perfect islands, i. e., coral, sand, and mud have been thrown upon and completely buried the large mass. But none of these are yet clothed with vegetation, much less inhabited by either animals or men. Next come the larger, inhabited islands of the line of keys [where it has been picturesquely remarked that horticulture is carried on with a butcher knife and a crowbar]. On cutting into these the same structure as described above is revealed. These are a string of wave-formed coral islands, and here was once a line of living reef, but the corals have long ago died, because cut off from the open sea by the formation of another reef farther out. Next comes the southern coast. Examination of this reveals the same structure precisely. Here, then, was the place of a still earlier reef. The formation of barrier reefs without subsidence may be accounted for thus: From

[1] The coral making polyp is as much an animal as a cat or a dog is.—Dana on Corals and Coral Islands, third edition, p. 20.

[2] Let it not be said that this is "far-fetched." Listen to Mr. Langley, the secretary of the Smithsonian Institution, in his "New Astronomy:" "The explosion which occurred at Krakatao August 27, 1883, was heard, according to official evidence, at a distance of 1,800 miles, and the puff of its air wave injured buildings 200 miles distant, and, we repeat, carried into the highest regions of the atmosphere and around the world matter which it is at least possible still (1892) affects the aspect of the sun to-day from New York to Chicago" (p. 185).

[3] Compend. of Geology, p. 101.

the manner in which, by my view, the bases of the coral reefs have been formed, viz, by deposition of sediment, there must have always existed a very soft, shallow sea bottom. Along such a shore line a fringing reef could not form, because the chafing waves stir up the mud. But at a distance from the shore, where the



1. Nautical chart of the Florida Reefs and Bahama Islands (Hydrographic Bureau, U. S. N.).

2. A diagrammatic map of Florida. *a* in both diagrams represents present coast, *b* present keys, *c* present reef, *d* present shoal water, *e* present navigable waters, *f* present flats, called flat woods, *g* Okeechobee seeping out to the south through what are now called the Everglades, *h* the backbone of the peninsula. After LeConte, with slight modification of the extent into the interior of the portion marked *f*, the axis of the St. Johns (flowing north) and Kissimmee (flowing south) rivers being considered to have been in the past what the so-called Indian and Halifax rivers (mere salt-water lagoons, fenced off by outlying sand bars or keys) are now.

3. Is a cross section of 2.

water is 100 feet deep, and the waves no longer touch the bottom, a line of reef would form, limited on the inside by the muddiness and on the out or ocean side by the trough of the Gulf Stream. This would be in form a barrier reef, but wholly different in signification from those of the Pacific.

But Professor LeConte was merely interested in the contributions of animals to the geology of Florida so far as those contributions served to check the too wide application of the theory that as a mountain in the South Pacific sank into the waters of that sea the coral animals built up a ring around the sinking mass, which, starting on the submerged and sloping side of the mountain, grew upward and inward as the mountain sunk, and when the mountain had slowly disappeared beneath the surface became its sepulcher—a narrow ring of verdure-dotted coral a dozen miles or more around separating the quiet surface of a lagoon from the wind-tossed waters of the open sea.[1] But imagine this open sea to be replaced by land as flat, though not as easily moved by the wind, as the surface of the sea; imagine the coral band that holds the lagoon to be replaced by a ridge of sand covered with cypress or even less amphibious trees, and the greenish water exchanged for one stained blue black, and the atoll of the South Pacific is changed into the rim and basin of a Floridian lake. As wind and wave drive floating matter upon the coral reef from without, so the same agencies from within drive upon the shore of the lakes in the prairie regions of the Kissimmee the sand and decaying vegetable matters that their shallow bottoms ever give up to the waves created by the heavy winds that sweep across their surface. But behind the ridge thus formed there is a depression something like that existing between the coral reef and the sinking mountain peak, which is sheltered from the wind by the rim of the basin and kept moist by the drainage water of the surrounding land, which is cut off from the lake by this rim. In that climate all the elements for growth of coarse vegetation—heat, moisture, and quiet—are present and there soon appears over the whole surface of the white sand a skin of black. Where flats have existed such as those through which a tortuous Floridian creek empties itself, or joins two lakes, the conditions are such that beds of muck 2, 3, 4, or more feet are created, which when the lakes are drained are exposed to view. The soluble portion of this decayed vegetation or humus, though brown in color, lends the lakes under certain sky effects there a dark-blue shade, but does not appear to contaminate their waters.

But this water-logged humus is quite different from the leaf mold of the forest. No mosses add nitrogen to its substance while it is sopped in water; no nitrogenated air circulates within its body; no trees prevent the fierce chemical action of the sun upon its spongy surface. Cracks wide enough for a man to thrust his arm in seam its body, and it will smolder for weeks when ignited from the fires set to the tree like weeds that naturally spring up when it is by drainage freed from stagnant water. The whole mass halts between a coal bed and a garden soil, and as yet is neither. How different the humus of the forest-covered mountain sides. A myriad of bugs and worms aerate the mass and knead it with the geologic soil upon which it rests. Thus it acquires a smaller range of variation under extremes of extension by moisture and of shrinkage by dryness than it naturally possesses, and though it works its way slowly down into the valleys, enough is still retained upon the slopes to insure the existence of the mountain forest. Thus, while nature is tirelessly making "muck" upon the banks of the Gulf Stream opposite Florida, man upon our mountain side is with equal industry baring the rocks of "humus" by processes which two hundred years ago had left no alternative to the governments of Europe but to interfere to prevent a national calamity.

With some hesitation as to the entire propriety of its introduction in support of the difference between swamp muck and forest humus, but still, as suggestive,

[1] The individual characteristics of particular atolls and of the lagoonless atolls in general are all fully described in Mr. Dana's Corals and Coral Islands and in Mr. Darwin's The Structure and Distribution of Coral Reefs, first edition, 1842; third, 1889.

the following analysis of gas taken from a (wet) manure heap about 3½ feet deep is given:[1]

	Upper part.	Central part.	Lower part.
Carbonic acid (CO_2)	21.6	31	37.1
Nitrogen	78.4	35.5	4.9
Marsh gas (methune) CH_4		33.5	58
	100	100	100

This explains the difference between "muck" and "humus." It is a difference between the generation of two forms of carbon, one of which (carbonic acid) in daylight is useful to the leaves of plants but not to the roots, and nitrogen, which is useful to the roots, no matter how theory fixes up the modus of the process, but not to the leaves.

"The universal opinion," says Professor Liebig "that the substance called humus is extracted from the soil by the roots of plants for the purpose of assimilation is untenable, for there are the most conclusive proofs that humus in the form in which it exists in the soil does not yield the smallest nourishment to plants." Which statement he endeavors to substantiate by applying the arithmetic of the chemical laboratory to the "amount of basic metallic oxides, potash, soda, lime, magnesia, iron, and manganese" produced annually, "on the average," by the growth of firewood on an acre of Hessian pine trees.[2]

Against this argumentation of the brilliant chemist the accurate and cautious experimenter Saussure may be quoted: "Plants do not take all their mineral food out of solutions such as those which are artificially made by dissolving hydrocloride of lime, iron, or manganese in pure water; but they take them for the most part from compounds which we are unable to form, namely, out of such compounds in which these salts are chemically combined with oxygen, hydrogen, nitrogen, and carbon in humus extract, a fact that can only be revealed to us by an examination of the ashes of the plant." As there is nothing in the ingenious guesses, though based on remarkable experiments, which have affected Saussure's statement made in 1804, and as in the "arid soil" of the desert, though there is only one-fourth as much humus as in a "humid soil," that arid humus is three times richer in nitrogen than the humus of the "humid soil,"[3] the statement of M. de Saussure will be adopted as the truth so far as known for practical agriculture, but see pp. 957 and 960.

Man nevertheless is not the only agency that denudes the mountain sides of their mold. In many parts of England a weight of more than 10 tons of dry earth passes annually through the body of the worms contained within the boundaries of a single acre and by them is brought to its surface. In woods, if the loose leaves of autumn are removed, the whole surface will be found strewed with the castings. A professor in charge of the State forests near Nancy, France, has pointed out this circumstance as a beautiful example of the natural cultivation of the soil. Thus, on hillsides, a considerable quantity of elaborated earth is moving down into every valley.[4] But if the trees are there moisture is there, and with moisture mosses, fungi, and worms, the agricultural implements of nature. Von Hensen placed two worms in a vessel 18 inches in diameter, which was filled

[4] Darwin, Formation of vegetable mold, pp. 305, 5, 308. This book was preceded by a paper in 1837, which was not thought very highly of in some quarters. After Darwin, Hensen is connected with the propagation of the idea.

with sand, in which fallen leaves were strewed, and these were soon dragged into their burrows to a depth of 3 inches. In six weeks an almost uniform layer of sand four-tenths of an inch in thickness was converted into humus by passing through the alimentary canals of these two worms. But it is not by flower-pot experiments alone that this matter has been proved.

"On December 20, 1842," says Mr. Darwin, "a quantity of freshly broken chalk was spread over a part of a field near my house which had existed as pasture certainly for thirty years. The chalk was put there to note the distance down it would be found at some future time. Twenty-nine years after (November, 1871), a trench was dug across this part of the field, and a line of white nodules could be traced in both sides of the trench at a depth of 7 inches from the surface. Excluding the turf, the mold had been thrown up at an average rate of two-tenths of an inch a year. Another part of the same field was mossy, and, as it was thought that sifted coal cinders would improve the pasture, a thick layer was spread over this part either in 1842 or 1843 and another layer some years after. In 1871 a trench was dug, and many cinders lay in a line at a depth of 7 inches beneath the surface and another line at a depth of 5½ inches parallel to the one beneath. Had the land been plowed land, instead of being permanent pasture," continues Mr. Darwin, "the accumulation of mold in that field would probably not have been

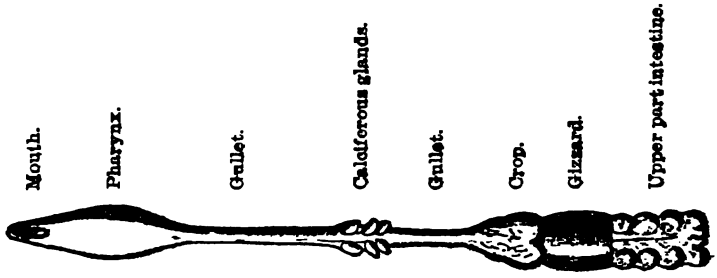

Diagram of alimentary canal of an earthworm (Lambricus), after Lankester.

so fast; had it been thicker, it would probably have been slower." He had a sloping field called the "stony field," the large stones of which he doubted in 1841 if he should ever live to see the worms cover up when he put it down to pasture to start the process going. In 1871 a horse might gallop over the field and not strike a single stone. The thickness of the matted turf was not quite half an inch, then came 2½ inches of stoneless mold, then coarse clayey earth full of flints, such as could be found in the fields around. The average rate of the accumulation above the sinking stones was not quite 1 inch in twelve years, or 0.083 inch a year.

The form of this extraordinary agricultural animal is well known. With the exception of the fisherman, few care to come in contact with the creature, and its defenselessness is proverbial. The inside of the worm is not more attractive than the outside, as may be seen from the sketch herewith annexed. Through this train of vital mechanism pass enormous quantities of dirt, which is discharged by the animal at the mouth of its burrow. Half-decayed leaves, petioles, peduncles, and decayed flowers are likewise swallowed and the nutriment they contain likewise assimilated. The leaves are drawn into the mouth of the burrow and are moistened with a sort of saliva, which acts on the fresh leaves in a remarkable manner, changing the green color of the chlorophyll-bearing cells to a brown. The saliva is the same as the pancreatic secretion of the higher animals.[1] It operates with an alkaline reaction and converts vegetable cellulose into soluble carbohydrates and is, in fact, a ferment. The calciferous glands excrete lime.

Farmer and gardener are apt to be deadly enemies of this harmless little animal.

[1] Léon Fredericq, quoted by Darwin in his Formation of Mold, and by Bunge in his *Physiological and Pathological* Chemistry, tenth lecture.

It was thought that it feeds upon the tender roots of plants. Upon this point the testimony collected experimentally by Wollny may be cited.[1]

1. In no one of my experiments have the plants suffered the slightest injury.
2. Other things being equal, the soil filled with worms was very noticeably more fertile than those free from worms.
3. The pulverization of the soil by the work of the worms lessened its capacity to hold water and increased the amount of air beneath its surface.
4. The work of the worms favorably altered the mechanical properties of the soil by making it more porous.

Hensen having stated that the burrows made by worms were the paths of the roots of plants, experiments were undertaken by Mr. Méhured Djémil, of the experiment station of the University of Halle, to test his conclusion. The experiments appear to demonstrate the error of this incautious remark of Mr. von Hensen, as may be supposed on examining the illustration of the root given above. But the results obtained by the experimenter and tabulated by him are far more interesting in other particulars.

Eighteen tubes or pots being selected, each 40 inches deep and 8 inches wide, they were separated into two sets. In one set worms were to be placed, in the other no worms were to be admitted. Into three pots of each set were then placed a similar soil, "sandy clay;" into three more pots of each set was placed a similar soil, "stiff clay," and into the remaining three pots of each set was placed a "clayey sand." The soils were air-dried, sieved, and then dried at a temperature of 212° F. The results were as follows for the leguminous plants (those for potatoes, beets, and vetch practically are the same and are not given):

THE ACTINIC ACTION OF THE SUN RAY.

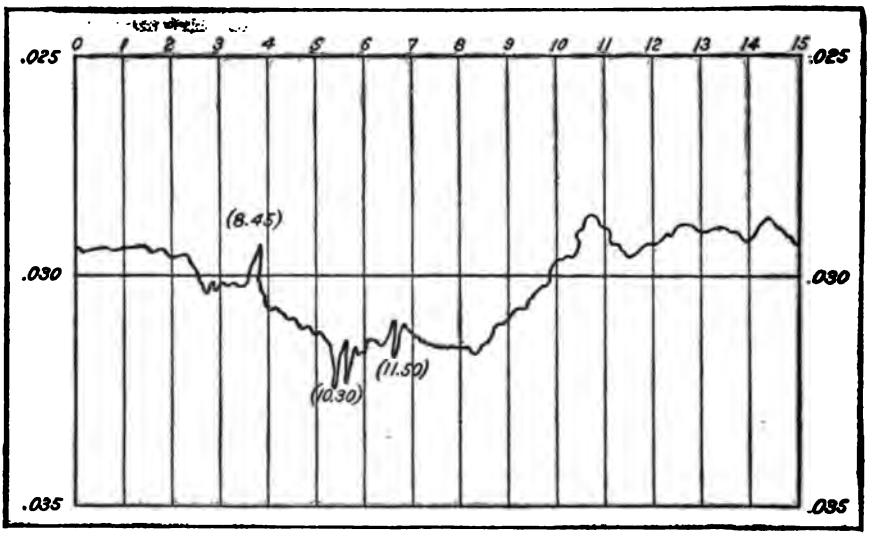
The value of water to vegetation in any form and of humus to vegetation in its higher or mammalian-nourishing forms has been noted. It remains to speak of light and heat, without which water is as sterile as a rock, if not, indeed, a rock when the thermometer is below 32° F. The icebergs that endanger the navigation of the North Atlantic carry neither palms nor lichens.

We shall consider the solar rays to present three activities, a light-making, a heat-giving, and a chemical-acting activity, which, though bound together like the strands of a rope, are yet separable in their effects. Plants breathe day and night,

[1] Zeitschrift für wissenschaftliche Zoologie, 1887, Band 17; quoted by Darwin.

but it is only in the light of the sun that their leaves disengage oxygen and assimilate carbon, which, as far as is known, is a chemical process. Attention will therefore be given to the chemical or "actinic" constitution of the atmosphere; in other words, the action of the actinic strand so to speak of the rays of the sun after they have entered our atmosphere.

If it were possible to follow our atmosphere upward until it edges off to extinction or where what there is of it is, as is said in the infinitesimal calculus, less than any assignable quantity, it would be found to be an atmosphere within an atmosphere, as the Gulf Stream is a body of water within another body of water. It is perfectly well known that a "perfect vacuum" in a tube will not pass electricity,[1] yet it is equally certain that there is at least a connection between the sun and terrestrial electric currents as those currents operate upon the surface of the earth, as the following incident will show: On August 3, 1872, Professor Young,[2] while observing at Sherman in the Rocky Mountains, saw three notable paroxysms in the sun's chromosphere or colored part of its atmosphere. Jets of luminous matter of intense brilliancy were projected at 8.45, 10.30, and 11.50 a. m., local time. The photographer of the party who was making the magnetic observations told Professor Young that he had been obliged to give up work as the magnetic needle had been "swung clear off the limb." Now, at Greenwich, in England, in addition to taking a daily photograph of the sun, they have in their cellar an apparatus which traces the fluctuations of the daily "magnetic vertical force." To the astronomer royal at that institution Professor Young immediately wrote, and, correction for the difference in time being made, here is the reply:



Greenwich Observatory (England) magnetic observations on August 3, 1872. The tremulous line is made by a magnetic needle carrying a small mirror, whence a spot of light is reflected upon a strip of photographic paper, kept continually rolling before it by clockwork. If the needle is still, there will be a straight line on the paper. If the needle shivers, the light spot vibrates with the motion and the line becomes sinuous or more and more sharply zigzaged as it trembles in the grip of the unknown force which it obeys. [The illustration and incident are given by Professor Langley in his New Astronomy. Houghton, Mifflin & Co.]

[1] Radiant matter, Crookes. Lecture before the Royal Society of England.

[2] Professor of Astronomy in the College of New Jersey (Princeton). Author of the work, The Sun.

Although Professor Crookes could not send a current of electricity from one end of a glass tube which had been exhausted of all its atmospheric air to the other end, he found he could do wonderful things by discharging a current from the negative or cathode pole of an electric battery into a tube in which the air had been so far exhausted that it exerted a pressure of only one one-millionth of an atmosphere, the pressure of 1 atmosphere being capable of holding up a column of mercury 30 inches above the font or basin of mercury at the bottom of the column. He found that the stuff remaining in the tube struck out in a straight line, from which it could not be made to deviate any more than the force of gravity which strikes for the center of the earth can be made to deviate. He found that even a sunbeam acting on a pith ball striped longitudinally white and black and suspended in such a vacuum would make the ball revolve with such rapidity as to jeopardize the safety of his delicate apparatus, just as the world, or, rather, its atmosphere, might be supposed to be made to spin by sunbeams, were it a pith ball in space, if it could be alternately striped from pole to pole with "light and shade." But when Mr. Crookes let more and more atmosphere into his apparatus he found the greenish phosphorescence change to purplish, that is to say, bluish, and that the current from the negative or cathode pole flowed to the positive or anode pole, as that was moved around, and could be deflected by a magnet.[1] "Could we float," says Professor Langley, "upon the uppermost layer of our atmosphere, the sun would appear to the spectator as bluish."[2] Possibly he might say, something on the order of the cold, cheerless blue of the hissing electric street lamp. But what these remarks are particularly designed to introduce and emphasize is the penetrating and dissociating or chemical effects of solar emanations, whether they be called sunbeams, radiant light, radiant matter, or X-rays.

The progress made by science, says M. Duclaux, professor of physics in the Agricultural University of France, leads us more and more to attribute to chemical rays a special action which is different from and, to a certain extent, independent of that of the heat and light rays, for they seem when passing through our atmosphere to obey laws peculiar to themselves. Landscape photographers well know that days equally warm or days equally luminous do not give the same chemical effects, and in northern lands, where vegetation is well known to be specially susceptible to the power of the chemical rays, growth proceeds more rapidly than in temperate regions, notwithstanding the fainter light and the lower temperature. To what are these differences due?[3]

To answer this question the thermometer will not suffice. That instrument, as its mercury rises, tells only that the mercury has become lighter, as all bodies appear to do when heated.[4] So Professor Duclaux selected a body which, being an organic body, is more or less dissipated by the action of the light, from association with the illuminating power of which, indeed, he found it impossible to separate the special chemical function of the sunbeam. This actinic measure was oxalic acid, easily formed from cellulose by heating with nitric acid. Two or 3 grams of the crystals of this acid are dissolved in 1¼ pints of water. In the proportion that the acid contents of this solution disappear, as determined by acidimetric measurements, the actinic or chemical effect of the atmosphere is told off, for M. Duclaux distinctly states "that neither the solar heat nor the heat produced in the

[1] Crookes's Lecture on Radiant Matter.

[2] The Sun, Young, 3d ed. (1890), p. 296; Professor Langley's account of some experiments, particularly p. 306.

[3] Atmospheric Actinometry and the Actinic Constitution of the Atmosphere, by E. Duclaux, professor of physics in the Agronomical Institute, Paris. Published by the Smithsonian Institution as its one thousand and thirty-fourth contribution to knowledge, by request of a committee of experts.

[4] Crookes's Lecture on the Mechanical Action of Light, "When the substance weighed was of a temperature higher than that of the surrounding air and the weights there appeared to be a variation of the force of gravity."

formation of carbonic acid [from the destruction of the oxalic acid] has any perceptible effect upon the solution as an index of the chemical action of the sunbeam, though on fine days half of the oxalic acid may be dissipated."

Now, in the first place, it will be found that the chemical changes produced in the oxalic-acid solution are influenced by the strength or amount of this acid dissolved in the water, by the depth of the vessel used to hold the solution, and the length of the exposure.

(*a*) The effect of the strength of the solution is shown by this experiment:[1]

	Standard strength.	One-half.	One-fifth.	One-tenth.
Acid dissolved in 1½ pints water.....grams..	63	31.5	12.6	6.3
Quantity of acid burned by oxygen of air .....per cent..	4	9	28	89

(*b*) The effect of the depth of the solution is shown by the following experiment, each vessel containing 10 cubic centimeters of solution one-twentieth of normal:

Acid burned.	Cone-shaped vessel.	Cylindrical tube.	Shallow, wide vessel.
	Per cent.	*Per cent.*	*Per cent.*
August 16 (8 a. m. to 3.30 p. m.)	29	.....	65
August 17 (8 a. m. to 3.30 p. m.)	24	14	97
August 18 (8 a. m. to 3.30 p. m.)	34	13	84
August 19 (8 a. m. to 3.30 p. m.)	31	14	87

As the cylindrical or "test" tube was put in the shallow, broad-bottomed vessel to secure uniformity of temperature, the result is at least accurate for those two in comparison.

(*c*) The effect of duration of exposure is shown by the following experiments performed on "Mont Dore," September 6, 1888, 8.30 a. m.: Four like vessels were exposed to the sun, and at the intervals stated below a vessel was withdrawn and the acid burned measured:

Time.	Acid burnt.
	Per cent.
After 2 hours	.....
After 4 hours	1
After 8 hours	10
After 10 hours	13

Observe the time lost in starting, but especially the rapidity of combustion from 12.30 to 4.30 p. m. Observe also that notwithstanding the lowness of the sun at 6 and 7 o'clock in September how fast the acid was burnt. "It is always so," says M. Duclaux, "whether the transformation of the oxalic acid be slow, as on Mont Dore, or quick, as I have sometimes found it at Paris." But this is not all. An exposure for one day of a vessel will render its oxalic acid contents more readily consumable the next than the contents of a vessel exposed for the first time. For instance, four vessels being prepared and exposed, two were examined at the close of the first day, and the amount of oxalic acid burned was carefully noted. The

[1] Saussure found that young plants died in an atmosphere of one-half atmospheric air and one-half carbonic acid gas but flourished in an atmosphere composed ½ common air and ½ carbonic acid gas. But in the shade the smallest quantity of carbonic acid gas added to the common air *was injurious.*

other two were left untouched and the next day were again exposed with two new vessels, and at the close of that day all four were examined:

	Per cent burnt.
Vessel exposed untouched for two days, September 2 and 3	68
Vessel exposed September 2 and examined at close of one day	10
Vessel exposed September 3 and examined at close of one day	24
	— 34
Favor of accumulated propensity	34
Vessel exposed untouched for two days, September 4 and 5	38
Vessel exposed September 4 and examined at close of day	12
Vessel exposed September 5 and examined at close of day	11
	— 23
Favor of accumulated propensity	15

In speaking of these matters in the present connection it must not be supposed that Professor Duclaux announced them as facts bearing upon agricultural chemistry or that he intended to present any analogy in discussing the conduct of oxalic acid, which occurs in almost every plant, under the action of the sunbeam, to the action of the sunbeam upon the union of nitric acid sent up by the roots to the leaf and the cellulose within the leaf when the leaf is sunlit. Professor Duclaux's tests of his apparatus nevertheless show how the organic acids in the leaf may be varyingly affected by the sunbeam, one day this way, another that; but as this is not exactly what he intends to prove by his apparatus, we may turn, in justice to him, to his demonstration of the fact that chemical effects of the sunbeam are independent of thermal effects thereof and are therefore not measurable by meteorological implements. "The principal lesson of my memoir," he says, "is that the actinic force of the day is not the same for the same day in different parts of the globe, and its effect increases more rapidly than the duration of illumination increases."

First, why does vegetation progress more rapidly in northern lands than in France? To Professor Elfving, at the University of Helsingfors, latitude 60° 10', where the day is fourteen hours long in September, and the sun 38° above the horizon at noon, was sent an oxalic solution and ten vessels exactly like those Mr. Duclaux was using in France. On five days the following observations were made:[1]

Actinic work of solar rays at Helsingfors.[1]

Date.	From 8 a. m. to 4 p. m.		All the arctic-circle day.	
	1887.	1888.	1887.	1888.
	Per cent.	*Per cent.*	*Per cent.*	*Per cent.*
August 27	42	56	55	75
August 28	50	50	65	68
August 29	53	55	61	71
September 2	74	49	87	59
September 4	77	49	80	67

NOTE BY MR. ELFVING: The difference between the first three days of 1887 and the two others of that year is great. It probably arises from the fact that the atmosphere was washed out by heavy rains on August 30 and September 1 and 2. I observed this effect of rain in March last. [The difference between the two years on the two September days is not explained. Both those days in 1888 had a "very clear sky."]

[1] It is proper to explain that in the first table the figures of the two years have been put together by the writer of this chapter, and M. Duclaux is in no way responsible for the combination if an improper one to make.

M. Duclaux had then his record made upon the bare table land around the Puy de Dome [illegible] of the English Channel a friend had made, at his request, a series of observations, which are as follows:

Actinic work of solar rays at St. Pierre le Port.

Date.	Work 8 a. m. to 4 p. m.	Remarks.
1888.	Per cent.	
[illegible]	44	Clear weather till 2 p. m.; later, cloudy.
[illegible]	[illegible]	Haze till 2 p. m.; later, cloudy.
[illegible]	[illegible]	Very clear till 2 p. m.; later, cloudy.
[illegible]	25	Three-fourths cloudy till [illegible] a. m.; clear, 10 to 3 p. m.
[illegible]	23	Half overcast in morning, then clear.
[illegible]	[illegible]	Half overcast all day; slight fog.
[illegible]	[illegible]	Slightly overcast in morning, then clear.
[illegible]	[illegible]	Do.
[illegible]	[illegible]	Fine.
[illegible]	[illegible]	Do.
[illegible]	42	Warm; very close; clear.
[illegible]	22	Covered in morning and afternoon; clear from 12 to 3 p. m.
[illegible]	[illegible]	Overcast; rain [illegible] to 11 a. m.
[illegible]	24	Unceasing rain.

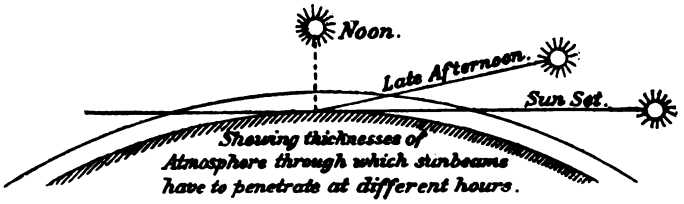
Here we have the register of the chemical work done by sunbeams within the arctic circle, the land of the "midnight sun," and by those that shine upon the seas that surround the land of the best European farming. Let us then supplement these self-evident figures with those taken by M. Duclaux at an altitude of 3,600 feet (1,100 meters) above the sea.

Actinic work of solar rays at Mont Dore, France, altitude 1,100 meters.

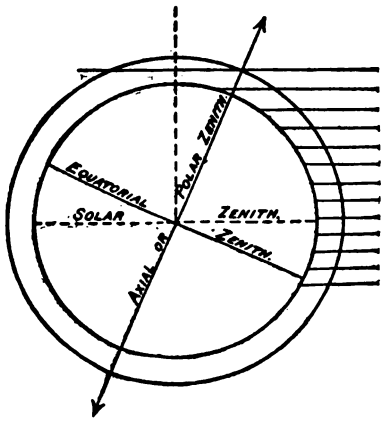
Date.	Work 8 a. m. to 4 p. m.	Remarks.
1888.	Per cent.	
August [illegible]	22	Fine day; cumulo-cirrus and cirrus.
August 30	15	Cirrus all day.
August 31	15	Large white cumuli.
September 1	15	Do.
September 2	10	Middling day.
September 3	24	Quite a fine day; many cirri.
September 4	12	Middling day.
September 5	11	Do.
September 6	12	Quite a fine day; some cumuli early.
September 7	11	Middling day.
September 10	11	Quite a fine day, with a few clouds.
September 11	7	Do.
September 12	18	Fine day; hot sun; a few cumuli.
September 13	25	Fine in morning; middling later.
September 14	15	Fine day; very warm.
September 15	9	Very fine day; as yesterday.
September 16	4	Middling day; warm and heavy.
September 17	29	Day divided between sun and clouds.
September 28	49	Rather a dull day; hazy, but no clouds.

M. Duclaux comments on these remarkable facts in these words: "What strikes us in reading these figures is their smallness, even on fine days. They are the smallest I have ever had to record in August and September for so many times. Yet September was fine at Mont Dore in 1888. But is it not noticeable how the character of the day and its actinic value do not square? Thus the very fine day of September 15 gave only a combustion of 9 per cent, while the slightly veiled day of September 28 gave a combustion of 49 per cent. This confirms my contention that we have missed our way in considering the chemical action of solar light as independent of locality and proportionate to time of exposure or as measured by meteorological instruments."

Those who have read Mr. Du Chaillu's Land of the Midnight Sun will not require any particular description of that romantic country or its people. It will suffice to say that for about one hundred and eighty-six days, during the summer period north of the equator, day and night are not so characterized by light and darkness as in more southern climes. The earth leans over toward the sun and the arctic pole points in such a way that the sun's rays are constantly striking the earth behind it, though for the remainder of the year the sun's rays never hit the pole at all. It was Sir David Brewster that showed the effect of this on the arctic atmospheric illumination and accounted for its redness. Mr. Lockyer, in illustrating this fact, remarks: "One form of aqueous vapor in our atmosphere exerts a powerful obliterating action on the solar light, commencing at the blue end of the spectrum and gradually creeping toward the other or red end."[1] But here is his diagram of Brewster's theory:



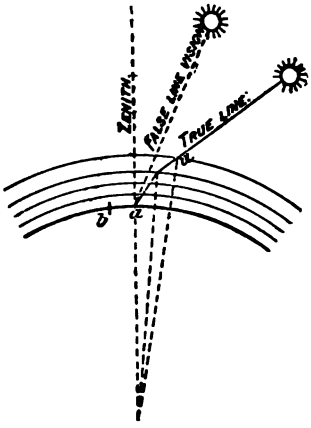
For the purpose now in hand it is necessary to arrange this diagram a little differently, reconstructing it so as to show the increasing thickness of the atmosphere through which the sun rays must penetrate in order to reach the arctic surface of the globe. Then the diagram will have this form for June 21 for some thousands of years yet, by which time the south pole will have gradually acquired the one hundred and eighty-six days of exposure to the sun now enjoyed by the north. If, however, we consider the sunbeam as striking the convex surface of the exterior of the atmospheric envelope of the earth, then the diagram would have to be again changed; for the atmosphere of the earth, being denser than the "void" of space, would act like a convex lens and focus the rays—let us say for convenience, at the center of the earth—as those rays came out of the "void." Rearranging the original Lockyer diagram to correspond with this suggestion of physics, we have a conception in which the course of the sun's rays through the artic atmosphere is shorter than in our preceding diagram; but they are refracted or bent and the value of the sunbeam is proportional to the angle and the manipulation given it by the atmosphere; that is to say, its "refraction" and its "dispersion" into its elements, that is, if any dispersion occurs at all.[2]



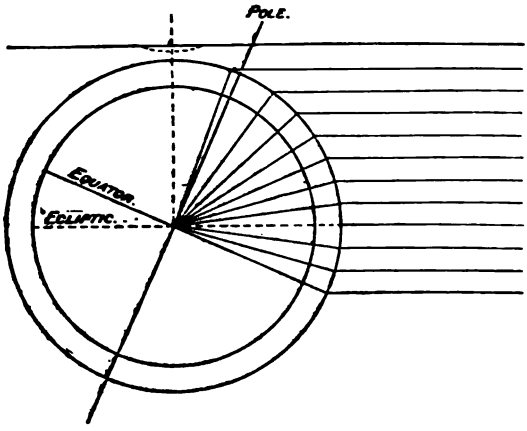
[1] Chemistry of the Sun, pages 37 and 38.

[2] Hankel is quoted by Professor Goodale (who in his Botany brings together the chief characteristics of the investigations up to 1885 and points out that while the spectrum absorption of chlorophyll shows up for the chemical or blue end of the prism-divided sun ray, direct experimentation is equally positive for the red end) to the effect that "the angle at which a beam of light strikes a plate of glass makes a noticeable difference in the amount of chemical rays which can pass through it. Thus, while at a vertical angle 81 per cent of such rays are transmitted, the rest being absorbed, at an angle of 60 degrees the amount transmitted is reduced to 71 per cent and at 80 degrees to 33 per cent."

There is in France an experiment station of a peculiar kind. It is called a station of agricultural climatology, and its object is to study experimentally the effect of sunbeams on vegetable life. Its director is the well-known astronomical writer, Camille Flammarion. Some singular results, though not new, have been proved at that establishment. It seems that if there is anything in the atmosphere that may cause the sun rays to tinge more toward the red of the spectrum, the

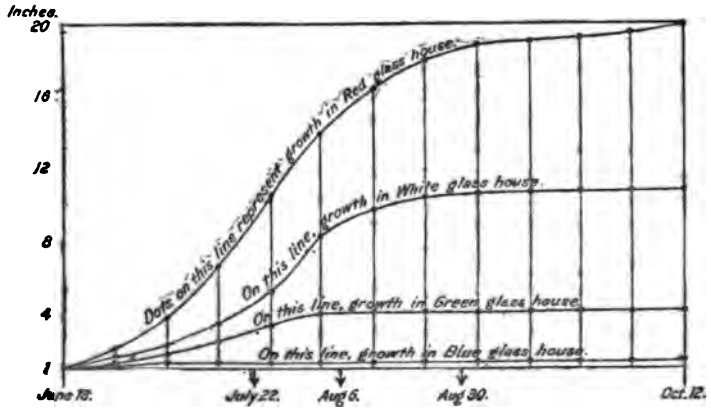


A ray striking our atmosphere is "bent" in so as to strike the earth at a instead of b. (After Fernet Traité de Physique.)



Arrangement of Sir David Brewster's diagram on the hypothesis that light is focused by the atmosphere.

effect is to hasten the growth and to elevate the sensitiveness, the nervousness, so to speak, of a sensitive plant to the highest pitch, while under blue effects the sensitiveness and the growth are reduced to a minimum. Here is the way four sensitive plants (*Mimosa pudica*) placed, respectively, in a blue-glass house, a green-glass house, a white-glass house, and a red-glass house grew during one hundred and twenty-two days:



And here are the plants—not, indeed, the four mimosas, but four lettuce plants, the one under white glass heading up, the one under red glass run up into the air, while its foliage drooped like a willow or a "novelty."

In these experiments only plants grown under white or red glass have borne fruit, and that the red glass grown fruit can not compare with that of the white glass. It is suggested that the most important part of this experiment is the definite establishment of the fact that white light will produce three times as much weight of roots as red light and one hundred times as much as blue light.

Effect of the different colors of the solar spectrum upon cabbage lettuce.

We have now passed in review the formation of the agricultural soil in which, as we shall see, the root imbeds itself and of the action of light upon the leaf, as spoken of in the first section of this paper, and we may now pass to the results of fifty years' experimentation at

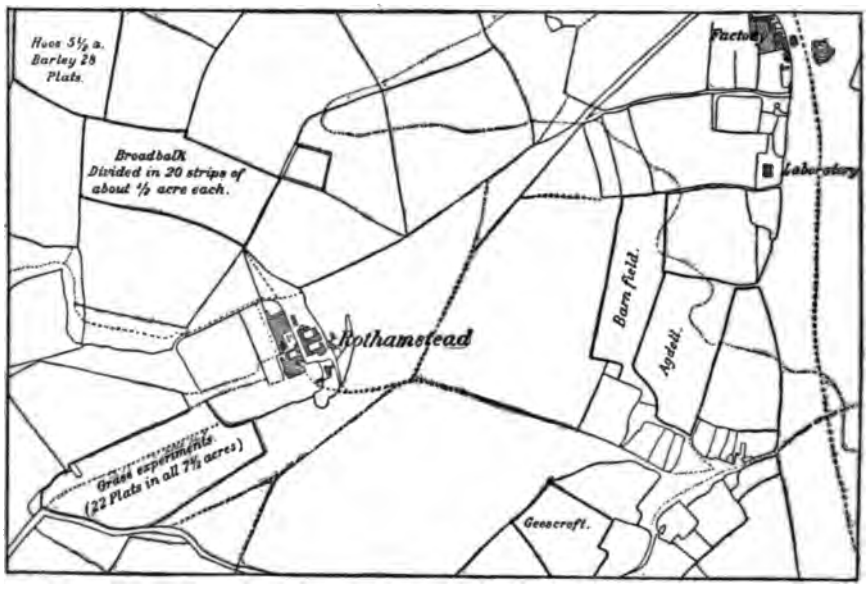
THE ROTHAMSTED EXPERIMENT STATION.

Rothamsted is a country place in Hertfordshire, 25 miles from London. Soon after coming into possession of the place Sir John Bennet Lawes began experimenting, at first in flower pots and then in the open field, and the researches of Saussure on vegetation were the chief subject of his study to his end. Of all the experiments made about 1834 those in which the neutral phosphate of lime was rendered soluble by means of sulphuric acid and the mixture applied for root crops gave the most striking results. In 1843 more systematic field experiments were commenced and the experimental station founded. The continuation of these experiments is insured by the gift of $500,000, the laboratory, and certain areas of land by Sir John. In 1889 trustees were appointed and a committee of management selected. The trustees are Sir John Lubbock, F. R. S., Lord Walsingham, F. R. S., Sir John Evans, K. C. B., treasurer of the Royal Society. The committee consists of nine members, four from the Royal Society, one from the

Chemical Society, one from the Linnean Society, two from the Royal Agricultural Society, and Sir John himself. Up to the present Sir J. Henry Gilbert has been associated with the founder in the conduct of the experiments for a period of fifty-four years. At first an old barn was used for a laboratory, but a laboratory was subsequently built by public subscription of agriculturists and presented to the founder in 1855. The staff has been one, two, and sometimes three chemists, two or three general assistants, a botanical assistant occasionally, two or three computers and record keepers, and a laboratory man and other help as occasion required.

There are now more than 40,000 bottles of experimentally grown vegetable produce, of annual products, of ashes, or of soils, besides some thousands of samples not in bottles. Nothing has been done at Rothamsted in the way of manure-feeding-stuff or seed-control.

The investigations have covered three inquiries, (1) agricultural vegetation, (2) agricultural characteristics of soil, and (3) manure as affected by the food and condition of live stock.



Agricultural vegetation.—For forty-two years experiments have been made in the park on the mixed herbage of permanent grass land. The plots vary from an eighth to half an acre, the whole area being 7 acres. The results to be watched for were pointed by the following considerations:

Assume a grass field. Its vegetable population is not uniform, but is as mixed as the human population of a Western State that has felt the full tide of a varied European and American colonization. The true grass family, the bean family, the composit family, and others, have representatives all struggling for existence. Now, it was known that wheat, oats, timothy, and other grain plants, or true botanical grasses, agree among themselves in demanding the same kind of manure. It was also known that plants of the bean and clover order—leguminosæ, as they are called—vary widely as to their demands, while crops of other

families—root crops (the cruciferæ, or mustard family), potatoes (belonging to the deadly nightshade or belladonna family, called solanaceæ), and others exhibit characteristics differing both from the grain-like or true grasses and still more from the bean and clover like plants of the great leguminosæ family, which is, next to the compositæ or sunflower-like family which is so largely made of weeds, the largest family of the vegetable kingdom. Now, which of this mixture of vegetable population is to be encouraged?

In the first place we have the popular artificial manures—nitrates, phosphates, and the alkali, potash—and next the manure of the farmyard. With these let us experiment to get the fifty families of the Rothamsted field to yield the agricultural product called hay in its best alimentary form. 1st., two unmanured plots, in all half an acre, show that seventeen true grasses, four leguminous plants, and the representatives of twenty-seven or more other families contribute to every 100 pounds of hay the following proportion:

	Pounds.
Grasses	65 to 70
Legumines	7¼
Other families	20 to 25

2d. Farmyard manure reduced the number of contributors to the hay permitted by the unmanured half acre, raised the contribution by weight of the true grasses, but lowered that of both the legumines and the other families. 3d. In order to illustrate the effect of the nitrogenous and other "mineral" manures applied in excessive doses for many successive years, it may be said, to take an extreme case, that the legumines have been completely poisoned or crowded out, and the other families nearly so, while about a dozen grasses have contributed from 95 to 98 per cent of the hay. The philosophy of this result is simple enough; any manure that favors an individual family or species of a family ruins natural competition. Nitrate of soda, or, better, equal parts of sulphate and muriate of ammonia (all nitrogenous manures), makes the true grasses luxuriant, but the beans and clovers which we have found getting nitrogen from the air are pushed to the wall by dosings of nitrogenous manures. "Purely mineral manures, supplying an abundance of potash and phosphoric acid, though reducing somewhat the number of the competing families, do not increase the luxuriance, though they favor the stemminess of maturation of the grasses, but reduce the percentage by weight of such herbage in the hay." But while the potash and phosphatic manures act thus on the true grasses that the nitrates nourish, they increase the luxuriance of the legumines and the weight thereof in the hay, while reducing the number of the miscellaneous competing families and their product. To close out this paragraph let us say, perhaps too dogmatically: Nitrogen makes grain-grass hay; phosphorus and potash, bean or clover grass hay, and farmyard manure, as we shall see in the next paragraph, makes hay.

Variety of vegetation adds great value to permanent grass land. Unmanured land produces 1 ton of first-crop hay to the acre having the most varied ingredients; potash will yield about one-half more of much less variety but considerably filled with leguminous plants, in fact, it produces the best mineral manure hay; but "mineral and nitrogenous manures together" run the yield up to thrice the amount of unmanured land, yet of the 95 to 98 per cent of the 3 tons of first-crop grain-family grass it produces 90 per cent is made up of four to six of the most freely growing and coarser species, characterized by great stemminess. To put the matter statistically, a horse would take into his stomach in eating the produce of an acre of unmanured pasture 7¼ pounds of phosphoric acid, 25 pounds of potash, and 30 pounds of nitrogen; in eating the produce of an acre of potash-dosed land, he would deposit in his stomach 18 pounds of phosphoric acid, 75 pounds of potash, and 50 pounds of nitrogen; while in consuming the 3 tons

produced by the potash-phosphate-nitrogenated field he would have placed at the disposal of his alimentary system some 30 pounds of phosphoric acid, 145 pounds of potash, and 108 pounds of nitrogen contained in that "very coarse, stemmy hay." "The general result has been," says Sir J. Henry Gilbert in his last annual report (1897), "to show that if artificial manures are largely or mainly relied upon certain descriptions of herbage will be unduly forced at the expense of others, and also the character of development of the plants will be materially affected. In order to maintain a due admixture of herbage on grass land mown for hay, farmyard or stable dung should be liberally applied; and it is also conducive to the same end to consume the second crop on the land with cake or corn. The more a good condition of the herbage is induced and maintained by such means, the more safely may some increased luxuriance, and therefore increased produce, be obtained by the judicious use of artificial manures. Provided dung be liberally used, it will not as a rule be necessary to apply potash artificially; but phosphates may be used advantageously in the form of basic (blast furnace?) slag and a nitrogenous manure in the form of nitrate of soda, which, however, should seldom be used at the rate of more than 1 hundredweight or at most 1½ hundredweights per acre." "Away from the Alpine pastures the blood of our stock can never be long maintained by foreign breeders," says the Swiss breeder, Wattenwyl. Let us pass to the experiments in the Broadwalk field (see map) on wheat.

For more than fifty years in succession wheat has been grown in the Broadwalk Field without manure, with farmyard manure, with various artificial manures. The period of the test is truly long and the results are surprising. Wheat may be grown for many years in succession on ordinary arable land (a little over an acre in all) without manure, so as to yield "nearly 13 bushels to the acre, or more than the average of the whole of the United States of America, including their rich prairie lands." But this statement must be accepted with caution. In the first place, the land was "kept clean," a very important consideration indeed; and in the second place, the climate of England may be a "wheat" climate, while the climate of the United States may be a "corn" climate. In the rice region of China wheat does not yield as heavily as in the north, where its culture is characteristic. Above the Yangtse Kiang, roughly speaking, it is not uncommon to get 64 bushels of wheat from an acre, below not more than 32 bushels.[1] But the Broadwalk field shows still other results. "Unlike leguminous crops, such as beans and clover, wheat may be successfully grown for many years in succession on ordinary arable land, provided suitable manures be applied and the land be kept clean." But mineral manures (phosphates, potash, etc.) alone will not do it, as Messrs. Liebig and Ville contended, nor nitrogenous manures alone, though they are more valuable than mineral manures alone; by combining them, however, a very much increased yield was given. In one case the product yielded by mixed mineral and nitrogenous manures was more than that by the annual application of farmyard manure of 14 tons to the acre. The inquiry naturally suggests itself, Was Liebig correct in speaking of the farmer who was to contract to supply to nature so many pounds of potash, so many of soluble phosphates, and so on, if she would promise to repay him usurious interest for his carting of foreign minerals upon his soil? As far as the exhaustion of unmanured soil goes, perhaps he was. It is estimated at Rothamsted that in the forty years elapsing from 1852 to 1891 there was an average reduction of the yield of a half an acre plot equal to one-

[1] The language used by M. Simon, in his La Cité Chinoise, p. 367, is this: Two or three days after the disposal of the fourth crop by turning it under a second working of the soil was made and then the fifth crop was planted in. This consisted of planting 7 meous (meou = a sixth of an acre) in wheat. Dans la région du riz le blé ne rend pas autant que dans la région plus septentrionale. Là il n'est pas rare qu'il donne 300 kilog. par meou, et même plus. Ici il ne rend que 150 kilog.

sixth of a bushel or to one-third of a bushel an acre, paying no attention to the seasons. Always referring to the full table as given in the annual reports of the Rothamsted station, let us venture to pick out four lines of its figures, not for the purpose of accurate study of its contents, but merely as an inducement to study them.

a 200 pounds (per acre) sulphate potash, 100 pounds sulphate soda, 100 pounds sulphate magnesia, 3½ hundredweight superphosphate, and 100 pounds muriate of ammonia.

In passing to consider the experiments in rotation in the Agdell field, it is pertinent to inquire what is the precise profit in growing straw and light wheat with mixed mineral manures.

There was a time when the panacea offered by science to agricultural distress was rotation in crops. It rested the land, it was said. There should be no more valuable contribution to agricultural practice than to ascertain the relative merits of the two or more fold course of rotation in keeping the land in good heart. At Rothamsted the four-course rotation was chosen—turnips, barley, beans (or fallow), and wheat—for the test which began in 1848. The results are important. They show that wheat, the staff of human life, possesses extraordinary agricultural vitality, but that root crops are a highly artificial product, possessing no agricultural stamina whatever, and will quickly revert to their lean and fibrous condition in nature if the soil in which they are grown is not constantly dosed with drugs or manure.

The Swedish turnips commenced the course on three plats, each of an acre; one constantly left unmanured, another treated to superphosphate of lime, the third treated with complex mineral and nitrogenous manures. The three plats were each divided into two, and upon one half the turnips were either fed to sheep or cut up and plowed under. A leguminous crop was sown upon each of these halves, but the other half was put to fallow. As this is somewhat confusing, the diagram is introduced. Thus, in the lowest rectangle *a* no manure was given to the plants, the root crop and foliage were carted away, and after barley, the second crop in each course of rotation, were planted beans or clover. On the other hand, in rectangle *b* exactly the same things were done, except that instead of planting beans or clover after barley, the plat was fallowed. But in rectangle *c* the first rotation crop (i. e., turnips) was fed upon the ground or cut up and plowed under, and the fallow followed the barley, while in rectangle *d* the root crop was fed as in *c*, but barley was followed by beans or clover. An analysis of

the results of the four unmanured rectangles is put into the form given in the foot note.[1] But far more interesting are the comments of Sir John Gilbert: "When various root crops are grown year after year on the same land, without manure, they soon revert to the uncultivated condition. In fact, without manure, the produce of roots was as poor in a four-course rotation as when grown year after year on the same soil." In regard to barley, it may be said that "both without manure and with mineral manure alone there was a larger yield of it in rotation than in continuous growth, but with mixed mineral and nitrogenous manure there was more produce when the crop was grown year after year on the same soil." As to the effect on the rotation of the clover and beans, it is said that "under equal conditions as to manuring the leguminous crops, especially the clover, bring much more nitrogen into the course than any of the other crops, but the amount of nitrogen so brought into the rotation is much greater under the influence of mineral manures, especially the mixed mineral and nitrogenous manures, than without manure. For the successful growth of leguminous crops, however, a liberal supply available, of, especially, potash and lime, is essential. Judging from comparable cases, the amount of nitrogen accumulated by the leguminous crops is much greater when they are grown in rotation—that is, when grown every once in a while—than when grown on the same land year after year. With fallow, instead of a leguminous crop, there is very much less nitrogen yielded in the rotation, and more liability to loss of it by drainage." As to wheat, "there was very much more produced both without manure and with mineral manure, and considera-

bly more with the mineral and nitrogenous manures, when it was grown in rotation than when grown continuously year in and year out on the same soil."

Taking the quantities of stuff produced by the barley and wheat in the rotation, it appears that each produced considerably more than either of the so-called restorative crops, that is, the roots, or the beans, or clover, but the supply of nitrogen within the soil placed within the reach of the wheat is increased by both the leguminous crops, but especially clover, and the fallow. Clover being thus confirmed as a restorative, or, as it was once called, an ameliorating crop, the experiments on clovers and other leguminous plants in "Hoos field" and "Geescroft field" require attention.

The experiments at Rothamsted upon clover are far from conclusive. Flower-pot experiments, and a patch of garden soil tell one tale, the Hoos and Geescroft fields another. Experiments were made in Hoos field on the growth of various leguminous crops year after year on the same land with mineral, and with mineral and nitrogenous manures, commencing in 1848–49. Red clover seed was sown twelve times in twenty-nine years, and the plant failed eight times out of the last ten trials. The results showed that when red clover was thus sown frequently on the same land, there was almost uniform failure. In fact, after the first few years practically no crop was obtained. In 1878, after the cessation of the trials with red clover, various other leguminous plants of different habits of growth, and especially of different character and range of roots, were sown on the (so to speak) clover-sick land. The result was that whilst red clover, which was included in the list of the new experiments, still failed, giving an average of only 22 pounds of nitrogen per acre per annum in five years of crop over seven years, the more weakly rooted and more weakly growing white clover, which had not been grown on the land for many years, gave an average of 47 pounds in six years of crop over nine years; the more freely growing and deeper-rooting vetch, an average of 75 pounds over fourteen years; Bokhara clover, 64 pounds per annum in eleven years of crop over twelve years; and the very deeply and very powerfully rooting lucerne an average of 160 pounds of nitrogen over twelve years. Here, then, when various other leguminous plants followed on the red-clover-exhausted land, they grew luxuriantly, and yielded much larger, and in some cases very large, amounts of nitrogen. Further, the surface soils gained rather than lost nitrogen.

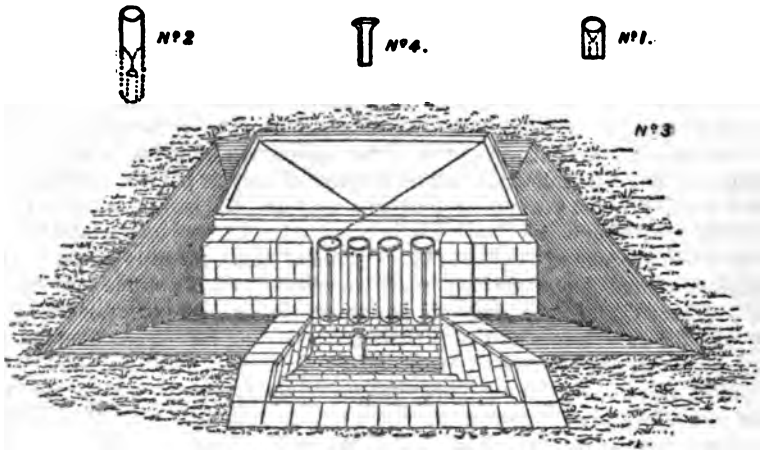
"Experiments have also been made with leguminous crops in Geescroft field. Thus, beans were grown year after year on the same land, without manure, with mineral manures, and with mineral and nitrogenous manures, commencing in 1847. The results showed considerable increase in the produce, and coincidently in the yield of nitrogen, by the use of mineral manures containing potash, though but little further increase by the addition of nitrogenous manures; notwithstanding that beans, like other leguminous crops, contain a much higher percentage of nitrogen and yield much more nitrogen per acre than grain crops. Further, by the growth of beans thus year after year on the same land, the amount of produce and the yield of nitrogen declined considerably, both being much less under all conditions of manuring in the later than in the earlier years. The results were confirmatory. As in the case of the growth of various other leguminous crops on the clover-exhausted land (in Hoos field), so now [in the Geescroft field] after the failure of the beans and decline in the yield of nitrogen in them, on sowing red clover, with its very different character and range of roots, on the bean-exhausted land, very large crops of clover, containing very large amounts of nitrogen, were obtained. Notwithstanding so much nitrogen was removed in the clover crops, the surface soil became determinably richer in nitrogen, due to accumulation of nitrogenous crop residue."

In spite of these facts, clover has been grown continuously for forty consecutive years on rich garden soil, though the plant showed "a much reduced persistence,

a considerably reduced amount of produce and of nitrogen, and with this a considerable reduction of the stock of nitrogen in the soil."

Rain and drainage.—The experiment stations of the United States, it may be supposed, have won their great achievements in the sphere of the destruction of noxious insects, the effects of animal food stuffs when taken into the stomach, and sampling fertilizers.

But they have also obtained some solid results in the line of soil physics, not to call it by its Gallic name of agrostology, a less practical question, no doubt, but still useful for the advancement of the science of agriculture, especially in the West. At Rothamsted the rainfall has been measured from the beginning, just as at Paris they have collected the rain falling every day for two hundred years.[1] But it has only been since 1877, that is, for the last twenty years, that the work has been wide enough to be of scientific value. The heads of inquiry are now "Rainfall," "Drainage," and "Loss of nitrogen per acre in drainage." The apparatus whereby this is effected is shown in the pictures.



VIEW SHOWING THE COLLECTORS OF RAIN GAUGE.

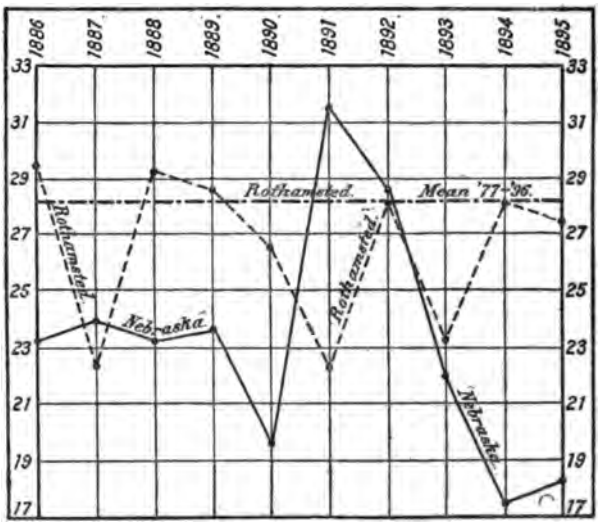
was an average annual loss of nitrogen in the drainage of 34.99 pounds through 20 inches, 30.58 pounds through 40 inches, and 33.47 pounds through 60 inches depth of soil; or, taking the average of the three gauges, of about 33 pounds per

Diagram showing comparatively the rainfall at Rothamsted and in Nebraska.

[Compiled from Rothamsted and United States Weather Bureau reports.]



NOTE.—The average at Rothamsted for 1851–1870 was 23.80 inches. The rain was collected in a "5-inch funnel." The 0.001-acre gauge shows that the funnel gauge falls short about 1 inch. The year 1891 in Nebraska appears to have been exceptionally moist and favorable to crops, while 1894 seems to have been greatly deficient in rain and yield, according to the weekly statements of the weather service in "Departures from normal temperatures and rainfall in Nebraska," 1896.

acre per annum reckoned as nitrogen, corresponding to an average annual loss of nearly 2 hundredweights of nitrate of soda.

"With reference to the large amounts of loss of nitrogen by drainage thus indicated, it is to be borne in mind that probably not more than an average of about 5 pounds would be contributed annually per acre from the atmosphere in rain and the minor aqueous deposits, exclusive of any condensation by the soil. Moreover, the soil of the drain gauges had been unmanured since 1868; but, being exposed to the access of air from below as well as from above, the oxidation of the nitrogenous matters of the soil and subsoil may be more active than in similar soil in its natural [not underdrained] condition. On the other hand, the soil was without any vegetation to arrest the nitric acid formed, whilst in some cases of fallow land which had been manured and cropped in the ordinary course, and which would therefore be in a much higher 'condition' than the soil of the drain gauges, as much or even more nitrogen as nitric acid has been found to be present in the autumn to the depth of 18 or 27 inches."

THE LIFE-PROCESS AND INSTINCT OF THE PLANT.

In the former part of these remarks we have spoken first of hypothesis and then of observational experimentation in agriculture. It is now proposed to speak of the agricultural plant, a subject which in agricultural courses of instruction is considered to be "botany." The knowledge of the origin of cultivated plants is interesting to agriculturists, to botanists, and even to historians and philosophers concerned with the dawnings of civilization, says Mr. de Candolle, and for such of them as desire to consult the literary record of agricultural vegetation that author's work is by far the best compilation. For those who seek to know why men have cabbages to eat instead of lichens and sweet potatoes instead of the swelled roots of some other form of the morning glory family the works of Mr. Darwin and others on the behavior of plants under domestication are necessary. Why the native Hindoo soldiers at the siege of Arcot could truthfully say to Clive that the boiled rice should be given to the English soldier, as the water in which it had been boiled would be nourishment in their stomachs,[1] can not be spoken of in this connection, for we are here concerned with the vital principle of the plant and its ability to care for itself, not with the digestive apparatus of the animal that eats the plant.

The plant sprouts, feeds itself from the air, and reproduces itself in growing, but all these activities are not primarily the work of the plant, but in particular of certain of its units. It is warrantable to say that the vitality of a plant is the sum of the vitality of its cells, modified, indeed, by the coordination of those cells to obtain nourishment freely and abundantly and the ability to use the energy elaborated from the nourishment thus obtained. Three theories of cell formation confront, not to say dismay, the inquirer. One turns upon the survival of the fittest, and each "physiological cell" or unit of the individual has the power of arranging itself into a special form (Spencer[2]) or to say the same thing differ-

[1] Macaulay's Life of Clive.

[2] In his argument in Principles of Biology (vol. 1, p. 182) Mr. Spencer makes these observations: "It can not be that the atoms of albumen or fibrin or gelatine or the hypothetical protein substance—the chemical units, so to speak—possess the power of arranging themselves into a special form, which I shall call polarity. Nor can such power reside in the mere cell form or morphological units, since the formation of a cell is to some extent a manifestation of the power. If, then, this organic power of arrangement into a special form is possessed neither by the chemical units nor the morphological units, we must conceive it to be possessed by certain intermediate units, which we may term physiological units." Again, in connection with heredity, he says: "Throughout the process of evolution two kind of units, mainly agreeing in the form in which they intend to build themselves, but having minor differences, work in unison to produce an organism of the species from which they are derived, but work in antagonism to produce copies *of their respective parents.*"

ently there are "gemmules" in each cell which flow to the sexual parts of the individual and strive concurrently, but perhaps not always harmoniously, to concentrate their energies to bring about the highest development of the individual's offspring (Darwin[1]). The second theory is based on logic, or "the formal laws of thought," and not on evolution in the Darwinian sense of that term, for it contends that if life was called from the dust in some remote past, as must have been the case on the Darwinian hypothesis, it may be again and again spontaneously created fiatlike and thus de novo form a new species of living organisms.[2] The third theory seems to falter between the facts of the first theory and the logic of the second, for it assumes a "germ plasm,"[3] which can neither be spontaneously created nor acquire new characteristics.

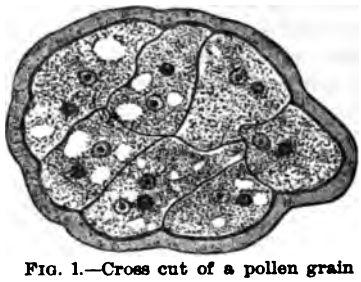


FIG. 1.—Cross cut of a pollen grain sac. The blank spaces are vacuoles. The large black dots are "vegetative" nuclei, the ringed dots are "generative" nuclei. (Highly magnified.)

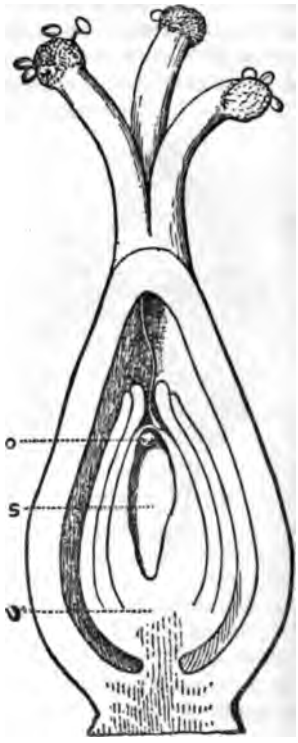

FIG. 2.—Diagram (after Gray) of a magnified pistil of buckwheat, which has an orthotropous (upright) ovule, *o*, oösphere, *s*, embryo sac, *v*, ovule. The pollen is represented as little balls on the surface of the stigma and one of them has sent down its tube through the style into the ovary. This tube has penetrated the mouth of the ovule until it lies upon the embryo sac near the oösphere.

THE DEVELOPMENT OF THE MALE CELL IN THE OVIARY.

Such are the hypotheses concerning the modus operandi by which new beings are created. The physical or visual facts in the case may be exposed as follows:

Let it be supposed that the dust called pollen has been emitted by the male organ of a flower, that is, by an anther, and a grain of that dust has been caught by the appropriate female organ, called the stigma, of a distant plant. Let it be further supposed that the pollen grain is roundish, like the spores of *Aspergillus niger*, mentioned on page 933. In a few minutes or hours that grain, being nourished by the sticky, viscid matter of the stigma, sprouts not upward into the air, like the Aspergillus, but downward away from the open air, like an anærobe, as shown in the illustration in the margin. The pollen is alive, for it has pushed a tube down into the ovary. The stigma is alive also, for it has secreted the juices that have nourished the pollen grain and helped along its penetration into the interior of the "pistil." We are, then, to look upon this growth of the pollen

[1] It is universally admitted that the cells or units of the body increase by self-division. But besides this means of increase I assume that the units throw off minute granules, which are dispersed throughout the whole system; that these, when supplied with proper nourishment, multiply by self-division and are ultimately developed into units like those from which they were originally derived. These granules may be called gemmules, and are collected from all parts of the system to constitute the sexual elements, and their development in the next generation forms a new being. They are not the physiological units of Mr. Herbert Spencer. This provisional hypothesis I call pangenesis [Animals and Plants Under Domestication, pp. 369–370].

[3] The Germ Plasm, a Theory of Heredity, by August Weismann.

grain as we have looked upon that of the Aspergillus spore, for the juices of the stigma are the "plasma" of the pollen. Thus antecedent to the fecundation there is a microbous growth, which sets up interior disarrangements, as will be shown, which eventually result after fecundation in the formation of a miniature plant. The strange thing about the matter is that the little plant may, when grown up, turn out to be greatly different from either the plant from which the pollen drifted or from the plant which caught and nourished the pollen on its stigma and then received the "being" of the pollen in its ovary.

Having thus remarked the manner in which the pollen seeks the egg for the purpose of fertilizing it, it yet remains to show the physical preparation in the ovary for the event.

PREPARATION FOR FECUNDATION.

In showing how the ovule or mother part of the plant prepares for the act of impregnation two things require particular attention. These are the development of the mother cell and the embryo sac, or embryonic egg proper, which transforms the contents of the sac into a miniature plant surrounded by food—that is, into a seed. But first, a moment's consideration of the development of the flower. For

this let us take a member of the milkweed family,[1] the shallow-wort, vince toxicum. The flower begins somewhat as shown in fig. 3. The undefined part continues to develop in the horn-like way in which the sepals started out, and at a "fifth stage" the flower shows the space that nature leaves for an interior growth, marked *f* in fig. 4. In the sixth stage all the future exterior or atmospheric parts of the flower have been formed, and for the present purpose the other "stage" of growth in fig. 6 will finish this introduction to the genesis of an embryo sac and its invaluable contents. We are now to consider what takes place in one of those little ovules of which two sets are shown back to back, using, however, another plant.

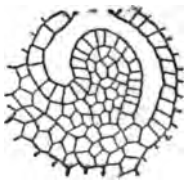

Fig 7.

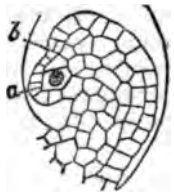

Fig. 8.

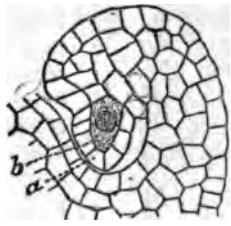

Fig. 9.

Beginning of an "Anatropic" ovule (fig. 7); appearance of a "mother cell" as the ovule turns upon itself (fig. 8); an enlarged view of same at later stage (fig. 9). [All after Martin.]

A short time before the floral organs of the aster, a member of the great compositae family, attain their maximum length there appears at the bottom of the ovarian cavity a rounded excrescence. This is the incipient ovule, the promise of a future seed.[2] At first the ovule is a mere mass of soft cellular substance like the interior of any young portion of a growing stem, but as it curves around and becomes turned up side down, as shown in the illustration of an "anatropic" ovule given above, a new kind of cell appears at the turning end of the ovule, which, surrounded by a single layer of ordinary cells, thrusts itself out from the main body. This is called the "mother cell" (figs. 8 and 9). The proceedings of

FIG. 10.—Exterior appearance during formation of an ovule of *Magnolia umbrella* during three weeks, about [after Gray and Maout et Decaisne's Traité générale de botanique].

this cell in expectation of the arrival of the pollen, as shown in Professor Gray's picture of buckwheat (fig. 2), will now require attention.

There is a question as to whether the wall or inclosure of the mother cell is immediately turned into an embryo sac or whether the sac is a product of the operations of its very peculiar contents. In the aster the mother cell proceeds to divide itself into three other cells upward and back of itself, then to reabsorb those three above it, and finally to consume the row of cells which cover it as it juts out from the body of the ovule like a peninsula, as shown at an early stage at *b* in

[1] Following Dr. G. Chauveaud, junior professor (agrégé) in the University of France, the work being done in the laboratory of botany of the Museum of Natural History at Paris (Ph. Van Teighem, director), in his article "Reproduction chez les Dompte Venin."

[2] Development of Flower and Ovule in Aster and Solidago, an interesting account of a series of independent researches by Mr. G. W. Martin, professor in biology, in Indianapolis, Ind.

fig. 9. Thus it finally has the appearance of the illustration in the margin. It is then completely victorious. It has demolished everything within reach save its foothold or base of supplies. The embryo sac is complete. Quite differently in the shallowwort (vincetoxicum) is this result effected. Like the aster's, the shallowwort's ovule puts forth a mother cell. This mother cell likewise increases in size, but at no moment of its existence is there the least trace of division by new cell walls, and the cell, at first like its neighbors, is enlarged and directly formed into an embryo sac. This direct transformation is very unusual for a plant having two seed leaves, though among the lilies, the tulips, and frittillarias, which have but one, the fact is not rare.[1] It is, however, by the lilies, which Mr. Grant White claims represent the immense threefold type of flowering plants,[2] that it is intended to show what the mother cell does when it is transformed into the embryo sac.

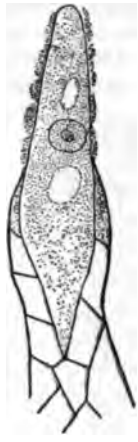

FIG. 11.—Consumption of the outside or cap layer of cells by the mother cell and completion of the embryo sac in the aster plant.

When the mother cell of the Turk's cap lily (*Lilium martagon*) has gathered headway, there may be noticed, in addition to the usual network structure, certain threads or streamers, which however vary in their lay with regard to different mother nuclei of the same stage of development. Some, as in fig. 1 of Plate I, form a sort of spherical envelope around the nucleus; others, as in fig. 3, stand out from it like bristles from a globular brush. In other cases the nucleus presents the appearance of fig. 2. But later on these differences vanish and the contents of the sac outside of the nucleus and the contents of the nucleus are mixed in the way shown in fig. 4. It will be seen how the bundles converge in fig. 4 without any apparent regularity. In fig. 5 this is changed and a sphere is formed having the contents of the mother nucleus at the equator. In fig. 6 this equator is separated and two new or "daughter" nuclei are formed. These also separate and form four "granddaughter" nuclei, so to speak, and these also separate and form eight "granddaughters," four of which are in the upper end and four in the lower end of the embryo sac, which has greatly elongated. In the case of the aster one of the upper four moves down to the middle of the sac, and then one of the lower four moves up, both consolidating into one (fig. 12). This leaves a trio of cells as shown in Plate II (fig. A). Fig. B explains the visual process of the transformation of the cell into an egg that will develop into a seed as shown in the footnote.[3]

B, when it becomes the oöspo Fig. B shows the female element absorbing the male. A view of the case where this absorpti or coalescence does not happen is shown in the case of *Lilium martagon*. [The lower figures a *after Mottier*, the upper is used by Professor Mussat of the Grignon Agricultural School *France.]*

THE VEGETABLE CELL.

The first material fact in the vitality of a plant considered apart from earth and air is the cell; the next, the circulation of the sap. The one is dead matter vitalized, the other disobeys the law of gravitation. Both being enigmas, a brief description of them will suffice. The vegetable cell is distinctly, though not quite universally, distinguished from the animal cell by two chemical features. Its cell wall is composed of cellulose, and it contains chlorophyll. Some animals, of which there seem to have been myriads during the period of geological time called the Paleozoic or old age of the world, possess a substance resembling cellulose, which has been called tunicine from its being found only in the mantle which covers the

body of oysters and other mollusks. Some plants which it requires a microscope to see and a zoologist to claim for an animal have chlorophyll in their cells. Fungi and other "plants" have none. But let us restate these conceptions in another way.

When yeast is filtered, it is separated into a solid and a liquid portion. The latter, when examined with a microscope, will be found to consist of small sphere-like bodies 0.025 to 0.007 of an inch in diameter, each an independent, living organism, called a torula, floating in a liquid, from which it imbibes its nourishment, called a plasma. Again, if the green scum which is often observed collecting on

the roofs of houses and other such situations be mixed with water and examined under a microscope, it will be found to consist, mainly, of small bodies between 0.035 and 0.0001 of an inch in diameter. Let us compare these two "microbes," for both are plants, the first being a fungi, the second a chlorophyll vegetable.

Let us now speak of a living cell, as we have of a plant which grows, feeds, respires, and reproduces itself. We shall find a cell doing the same things. In short, the plant is only a form of government of a society of cells whereby the whole community strengthen the Protococcus-like individual and produce vegetative effects of a far higher order. Yet while the whole body continues to live the individuals are ceaselessly dying and reproducing. This balancing of life and death, which the cell system we call a plant masks, is related by Professor Bonnier in the inaugural lecture of his course on Vegetable Biology at the Sorbonne in 1887, following Hanstein, Loye,[3] and perhaps others.

This young cell, said he, pointing to an illustration, is wholly formed of thick (dense) protoplasm, which is marked off by thin partitions, while in the middle is the nucleus (cf. page 965, fig. 1, showing seven such cells in a pollen sac). Here is another illustration. The cell is now a little older. It has changed its form. Little drops of liquid are interspersed through the protoplasm. In this other illustration the structure is still further modified, the nucleus has now spread until it has almost reached the walls of the sac, and the protoplasm is only a thin layer between the sac wall and the nucleus. Here, finally, in the illustration I now show you there is neither protoplasm nor nucleus. (See Figure A of Torula above.) Those little partitions we found in the first illustration have been incubated, as it were, within the wall or sac of that mother cell. They have reached their utmost development, and the mother cell is dead. Thus a cell is born, grows, changes its form, reproduces itself, and dies. Yet this is not the only way, nor is it the most usual way of cell multiplication.[4] A cell may divide itself by an hour-glass constriction the protoplasm separates itself into two parts. But does the cell feed and respire? By methods both delicate and precise, it has been determined that the protoplasm takes in oxygen and breaths out carbonic acid, therefore it breathes and nourishes itself. When the cell has chlorophyll within its protoplasm it has the additional function in a strong light of breaking up the carbonic acid of the air and assimilating the carbon.[5]

---

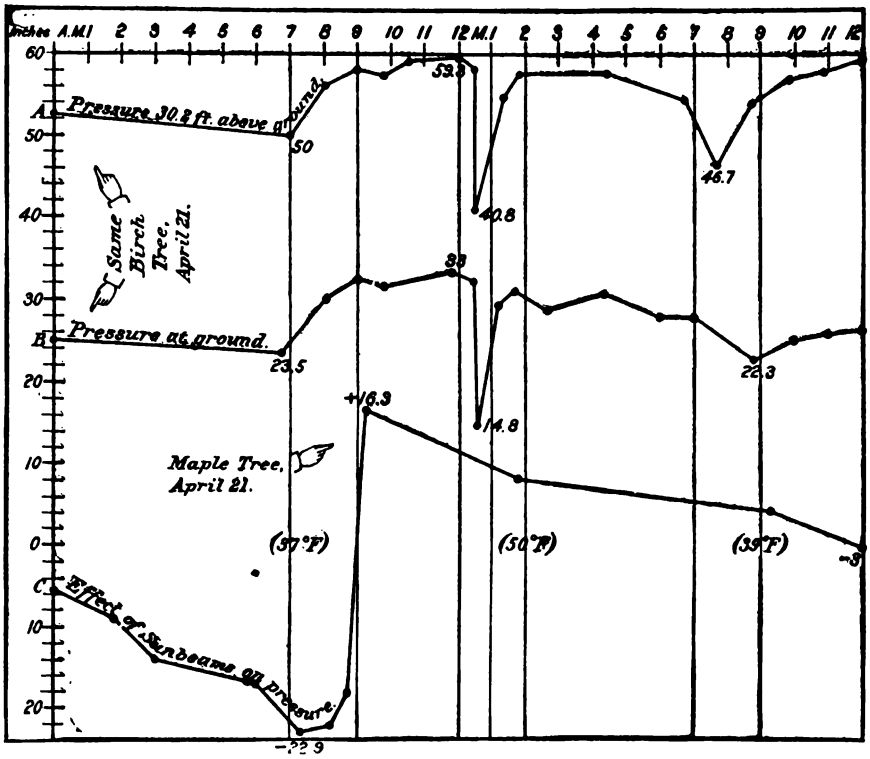
VEGETABLE HYDRAULICS OR THE ASCENT OF THE SAP.

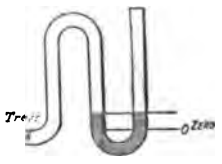
But if cells feed, as the professor at the Sorbonne tells us, how does the nourishment which comes from the ground reach them? In other words, by what charm do the cells in the uppermost branches of a towering pine call the water absorbed by the roots up to their lofty station, higher than the standpipes of our city waterworks? It has been urged that there is a pulling force caused by the evaporation of the leaves which causes the lower cells to hand up their water to the cells above them, while to account for the fact that if in summer a grapevine be cut off near the ground and a hollow tube fitted over the stump the sap will flow far up into the tube, another force—a pushing force—is imagined. Whatever truth this theory may contain, it can not prove itself merely by its simplicity of structure.



Perhaps in no country in the world is the tapping of trees for their sap so largely and systematically carried on as in New England, where there is quite an industry in maple-sugar making, though it is believed that the wild date tree is used in somewhat the same way in the oriental countries of the Indian seas. To those dwelling in New England, therefore, the flow of sap in the maple is a matter of fact that has long affected their business interests, and it has long been known to them that sap would flow from wounds in the wood of trees in spring; that the maple tree yields a large amount of sugar, and that the quantity and quality of the flow are affected by peculiarities of the season. It is said that few species of trees bleed at any time of the year when wounded, but several in the climate of New England, between the falling of the old and the pushing of the new leaves,

yield their juices when punctured, but lose that faculty when the young leaves appear. It has also been found that the sap flows readiest when freezing nights are followed by bright and warm days. But observe the diagram on page 973. Line A shows the fluctuation of a column of a siphon mercury barometer attached to a stopcock screwed into the sap wood of a tree at the level of the ground. Line B shows the fluctuation of a similar barometer 30.2 feet above. Line C shows the effect of the sun in starting up a pressure. All these observations were taken upon the same day, April 21,[1] and may be more particularly described as follows:

Line A: Pressure indicated by a column of mercury in a siphon-like tube in which whenever the mercury was at the same level in the two arms of the lower bend the pressure was put at zero. Line B: Pressure indicated by a similar gauge 30.2 feet lower down on the same tree trunk. Line C represents another experiment on a maple tree. The drop between 12 m. and 1 p. m. in lines A and B is due to the fact that on April 21 at 12.30 p. m. a hole was bored into the tree opposite to the lower gauge at the same level. In fifteen minutes 1 pound of sap had run out and both gauges had fallen to an amount equal to 19.27 feet of water. Upon closing the hole the mercury rose in ten minutes, as shown in the diagram. A stopcock having been inserted in the hole opposite the lower gauge, it was found that it could almost instantaneously make both gauges rise or fall in unison when closed or open. On the 11th of May the sap pressure indicated the weight of a column of water 84.77 feet high. The extraordinary rise just before 9 a. m. in line C is due to "the sun having warmed the tree." The minus figures merely state that the middle tube had more mercury in it than the tube with its mouth exposed to the air. The black birch (Betula lenta) was a fine and sound forest tree 6½ feet in circumference and 70 feet high; the maple, a healthy "shade tree" 5 feet in circuit and 60 feet high.

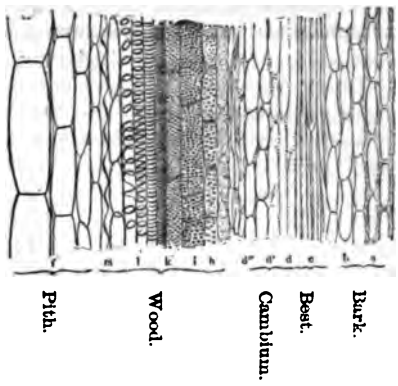


As soon as the foliage of the birch appeared the upper gauge came to an equilibrium ("zero") on May 14 and the lower on May 27. Too much stress, therefore, should not be laid upon its action, except so far as it shows the behavior of the sap on the 21st of April, 1873, as compared with a maple tree. But may it not be asked whether the tap root, for instance, of the birch is not a hydraulic ram or whether the whole tree is not a closed system of natural waterworks, a sort of vegetable artesian well, where levels go for nothing and vital forces for everything? That the maple tree should be so full of sap during the winter and should yield it so copiously during a warm day, if preceded by a freezing New England night, is another enigma. The cactus, a leafless plant of the arid region of New Mexico and Arizona, also yields a juice which is supposed to nourish the plant during the rainless portion of the year, and it may not be going too far to say that during the winter the leafless tree, like the sugar beet, perfects the juices its foliage has elaborated during the summer in order to flower and bear seed in the coming year. Fermentation has been suggested as the remoter cause of the growth of a lichen and a bean; and to it also is attributed the ripening of grape juice into wine. By analogy there would seem to be an opening for a proposition to the effect that fermentation or the ripening of the sap causes spring flowers. Be this as it may, an experiment with an annual plant shows that the expansive force of a growing fruit will lift more weight at midnight, when the foliage is exteriorly at rest, than at any other time of day.

[1] The Circulation of Sap, by Prof. W. S. Clark and the faculty of the Massachusetts Agricultural College in 1873.

VEGETABLE MECHANICS OR MOTION OF AND IN PLANTS.

On pages 928 and 930 it is shown that the leaf and the root are symmetrically arranged. The stem or wood portion of the trunk is likewise a symmetrical arrangement, as may be readily seen by the following cut:



The stem of a tree is surmounted by a bud, and the bud is but a series of expanding leaves. The movement of the stem, then, need not detain us long, for the very raison d'être of a tree trunk is to resist movement. Yet even the trunk up which the sap flows records a spiral movement. Observe the illustrations on p. 976. In the first the spiral arrangement on the twig is pronounced. The fact there shown is a branch of botany—phyllotaxy, or the rules of leaf arrangement. But it may be objected that the cherry-tree twig is not a palm which consists of a single growing bud. To such objection the "boot" of the sabal palm or palmetto will afford a ready answer, for it shows by the arrangement of the foot stalks of the decayed leaves how nature distributed those leaves so as to give them the most light.

It now remains to put in evidence the manner in which a bud is constructed and its method in extending the tree and fulfilling its purposes. In the first figure, p. 977, is shown a diagrammatic sketch of a flower-bearing bud and below it on each side two leaf buds. This diagram may be made to explain the growth of the tree yucca of the southern gulf coast, but considering the top bud alone the method of growth of the hemp agave called sisal is typified. This "succulent" after sending out its rigid century plant-like leaves for four or five years until the whole stands 4 feet or so high completely exhausts its life by throwing up a spike of bloom 12 or 15 feet, filled with branches bearing hundreds of little growing plants just like its own former but now defunct self, much to the disgust of those who in subtropical countries plant it for its tropical look and its indifference to full sunshine and absence of water.

Nor are these things all that may be advanced as testimony that the sap twines around the tree. On p. 977 are two representations, one of an alga (Riella helicophylla), the second figure of the cut, the other of the sap wood of a decaying pine tree (*Pinus palustris*) in a turpentine orchard; the sap wood seems wrapped round the heart wood like the bandages around a mummy. But it is of the leaf that it is necessary to speak.

The leaf of a plant is one of the most prodigious creations of nature. Professor Helmholtz may have said that any German oculist could make a better optical apparatus than is the human eye, but no one would ever have the impertinence to make such a remark about a leaf. They purify the atmosphere of a gas deadly to animal life and liberate one which promotes it. They are necessary to the production of grain and are themselves a food for cattle, and if the almost complete dependence of industry and transportation upon steam be considered, then in the form of coal or wood the leaf has brought about the so-called "industrial revolution; or the age that we live in."

"One of the most interesting facts with respect to the circumnutation of leaves is the periodicity of their movements, for they often, or even generally, rise a little in the evening and early part of night and sink again on the following morning. Leaves also turn at night, and the leaves of some few plants move either upward or downward when the sun shines intensely on them; but all these move-

ments," says Mr. Darwin, by whom these remarks were made, "are, we believe, of an essentially different nature." Before entering upon the separation of these classes of movements it is well to show what interpretation may be placed upon them.

People who live in houses in summer time are not apt to think how fast the earth cools off at night. Even in southern Florida in summer the cool night air is unpleasant; but when one approaches the equator or Central Africa, where in

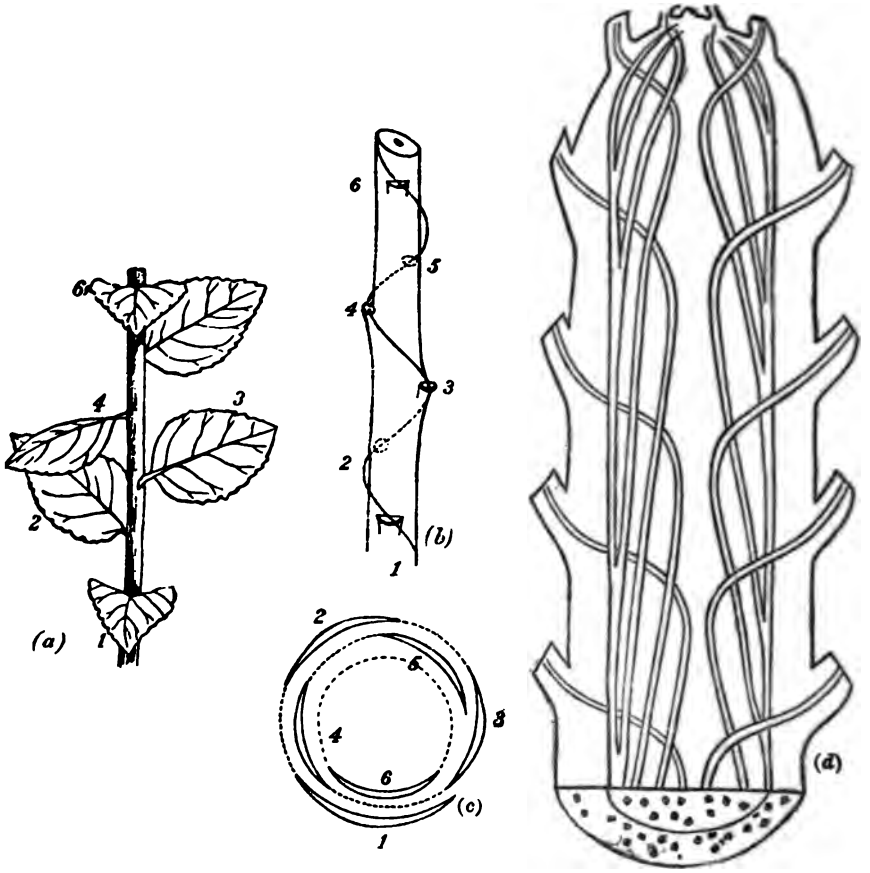


FIG. *a*.—Branch of cherry having six leaves; Fig. *b*, same defoliated, dotted lines indicating unseen part of spiral; Fig. *c*, representation of *b* as though it had been telescoped. (Figure adapted partly from Balfour and partly from Gray.)

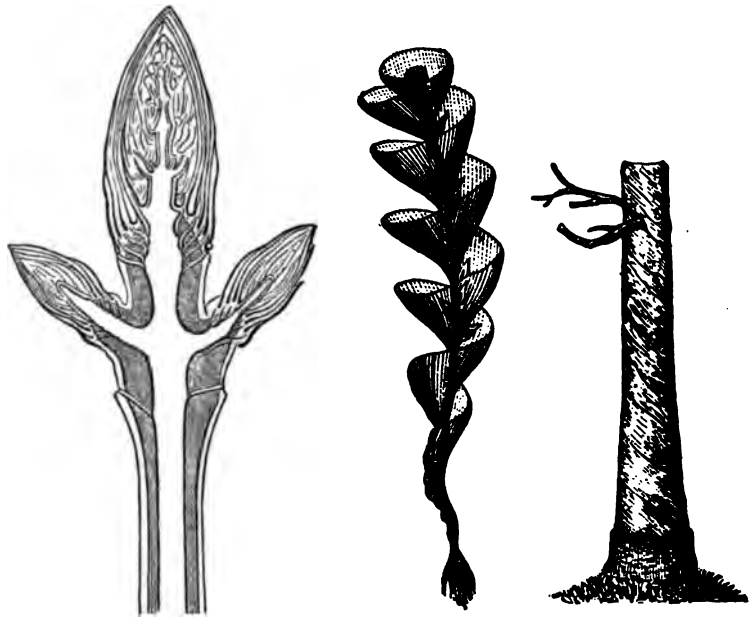
As was shown by Nägli, each thread in the leaf of the sample palm trunk type (aspidistra elatur in the diagrammatic illustration above. Fig. *d*) runs in spiral threads. He found the medium thread leading to a leaf, making 1½ revolutions in 6 internodes; in its sixth it had not, in its out course, quite reached the middle point between the center of the stem and the inner surface of the bark. (De Bary, quoted by Goodale.) (Compare Mr. Darwin's researches on circumnutation a few pages on.

daytime the thermometer is, to use Professor Drummond's expression of his feelings, "a billion centigrade," one seldom lies down in his tent with fewer than a couple of blankets and a warm quilt.[1] As broad leaves have none of these conveniences, they are obliged to fall off and perish in autumn and to protect themselves during the summer nights, when the earth radiates the heat acquired during the

[1] Drummond's Tropical Africa, p. 108.

day from the solar radiations which have passed through the atmosphere to it. The diagram given on page 978 shows how much greater the heat of the surface of the earth is than that of the air. In short, immediately the rays of the sun cease to warm the surface of the soil, the surface rapidly loses its heat to the cooler air or radiates it like a stove cools off when the fire within it has gone out, though the earth does not give back all the heat that has been shed upon it. Were that so, we would have no coal beds or forests in which are stored up some of the solar rays of former times.

"We (Mr. Darwin, and his son, Mr. Francis Darwin) exposed on two occasions during the summer to a clear sky several pinned-open leaflets of *Trifolium pratense*, which naturally rise at night, and of *Oxalis purpurea*, which naturally sink at night (plants growing out of doors), and looked at them early on several successive mornings, after they had assumed their daylight positions. The



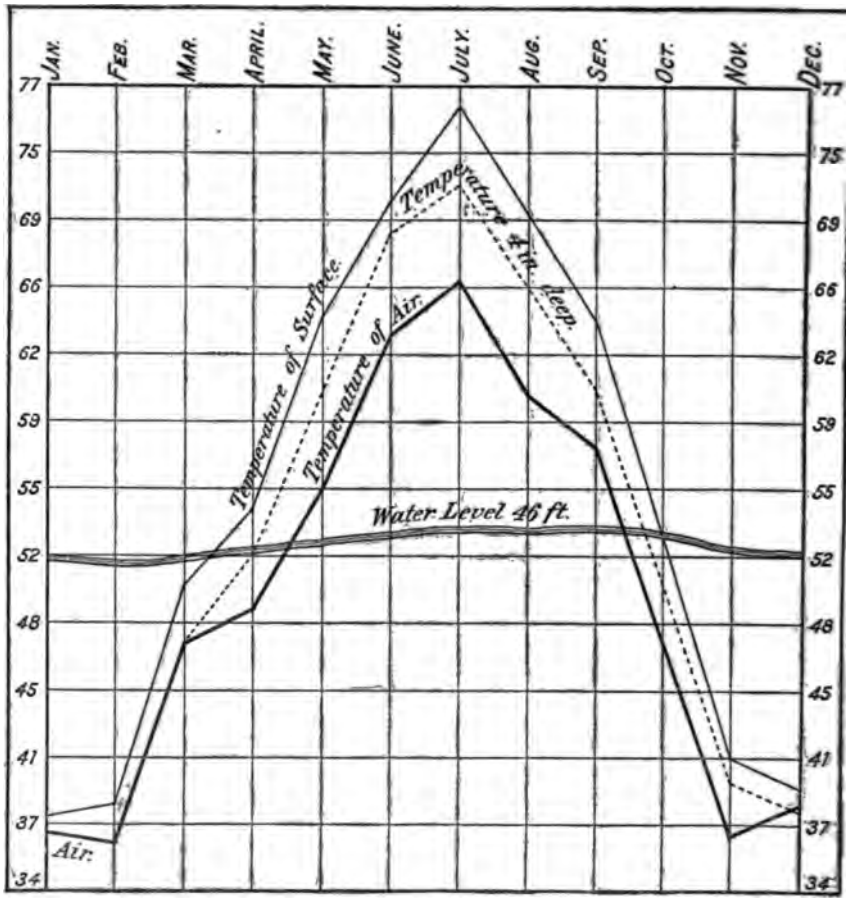
difference of the amount of dew on the pinned-open leaflets and on those which had gone to sleep was generally conspicuous, those having gone to sleep being sometimes absolutely dry, whilst the leaflets which had been pinned open were coated with large beads or dew. This shows how much cooler the leaflets fully exposed to the zenith must have become than those which stood almost upright, pointing up or down during the night. From the many experiments we have made, there can be no doubt that the position of leaves at night affects their temperature through radiation to such a degree that when exposed to a clear sky during a frost it is a question of life and death."[1]

It is a wonderful spectacle, on a warm, sunny day, to behold the leaflets of the *Averrhoa bilimbi*, one after another, sinking rapidly downward and again ascending slowly, while at night the leaves hang vertically and motionlessly down.[2] Indeed, Mr. Darwin was evidently impressed with *Averrhoa bilimbi*. It

[1] Power of Movement in Plants, pp. 293, 294.

[2] Power of Movement, p. 330.

is a plant of the Oxalis genus, and, like members of that genus, sleeps, moves spo taneously during the day, and responds to the touch, though in the Averrhoa a



Temperature of air and surface of soil in degrees Fahrenheit. From report of Station o Agricultural Climatology (1896), Juvisy, France.

these faculties, especially the latter, is strongly marked. A pot plant of this kin was experimented with. It was kept at a high temperature, and the leaf to b

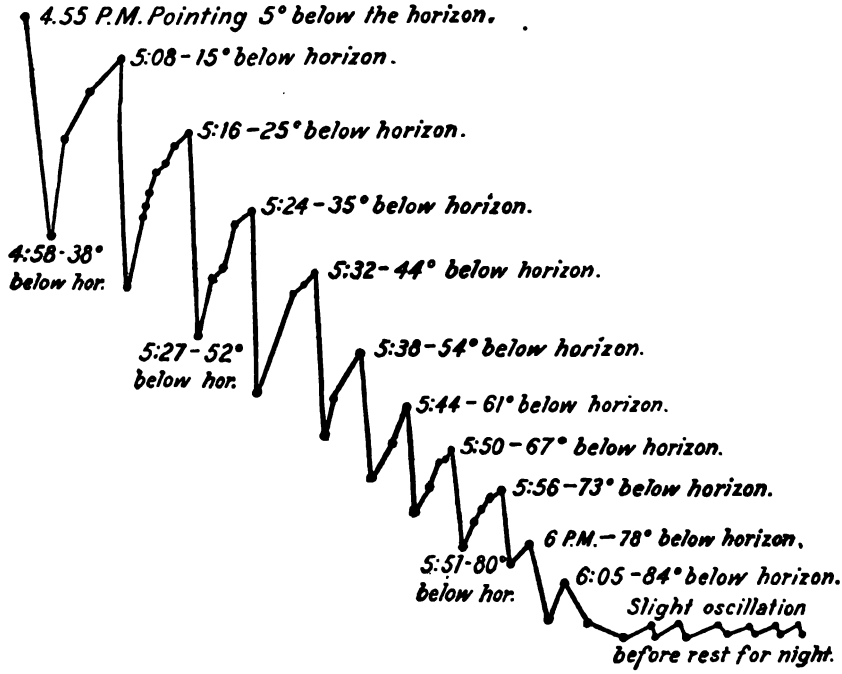
observed was pointed straight at the observer, though separated from him by pane of glass upon which he traces the movements.

The main leaf stock or petiole (*a*), which is in constant motion, was so stationed that the leaf stock of one of the leaflets (*b*) was at the center of a graduated arc placed behind it. To this leaflet (*b*) was fixed a fine glass filament in such a manner as to project like a continuation of the leaf stock and mid rib of the leaf. This filament acted as a pointer, and as the leaf rose and fell, rotating about its joining place with the main foot stalk (*a*), its angular movement could be recorded by reading off at short intervals of time the position of the glass filament on the graduated arc, and in order to avoid optical illusions the readings were made through a small ring painted on the vertical glass in a line with the leaf joint and the center of the graduated arc. In the following diagram we learn the course of the point of the leaflet during its evening descent, when going to sleep:



Let us see now how this leaf acted under a practically stationary temperature, but a quick change from bright sunshine to shadow (p. 980). This will illustrate the second of the three causes of the movements of leaves, to wit, some few plants move either upward or downward when the sun shines intensely on them, which has sometimes been called diurnal sleep.[1]

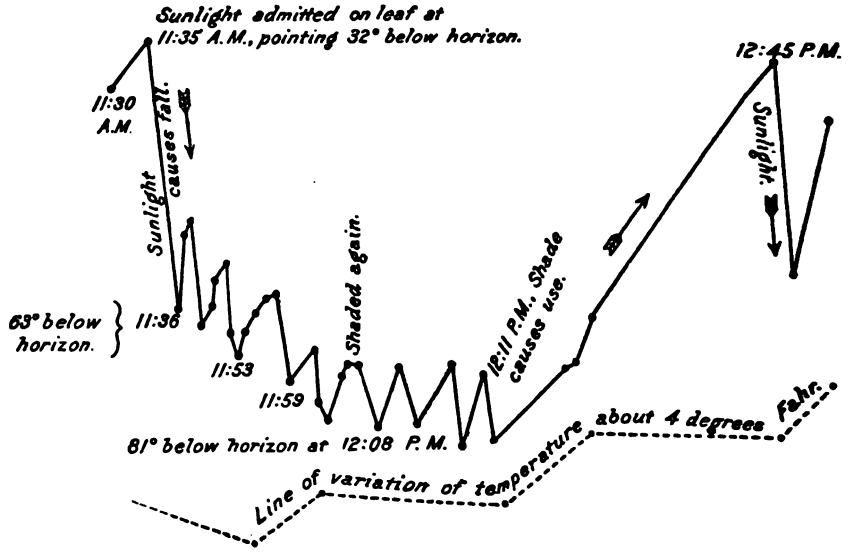
And finally here is the effect of a change of temperature of 14° F. during two hours and fifteen minutes in the heated part of the day (lower fig., p. 980). This may, with some modifications as to the nodding around of the leaf or circumnutation, be taken to illustrate the third cause of movements that leaves make.

The diagram upon the margin of the page 981 represents the circumnutation of a leaf of the well-known hothouse climber called *Cissus discolor*. The period of time spent by the leaf in scratching this outline outside of the hothouse in a tem-

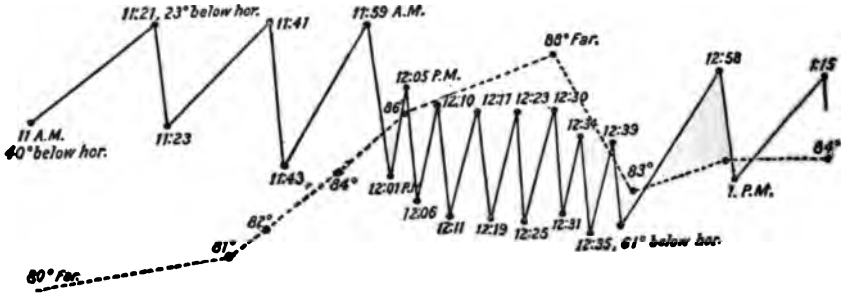
[1] Power of Movement, p. 281.

perature too cool for its vigorous action (59° or 60° F.) was thirty-one hours and thirty minutes—10.30 a. m., May 28, to 6 p. m. of the following day. The dotted line indicates the nocturnal movement.

Such are the movements of leaves. If, in attempting to show briefly the wonderful movements of mere plants, we have chosen specimens that are not found in the nearest field or woods, it is because the operations of nature are conducted



on such a delicate scale that it is only where she has accentuated them in some out-of-way plant that they can be observed. But even then nature is far from theatrical. There is no "last scene," nor does the curtain fall at the end of the first act upon a carefully arranged situation, except at rare intervals, and then a tragedy is played upon the grandest scale imaginable: Half of a mountain, such



as Krakatoa, is tossed into the air and 70,000 people are destroyed, a Pompeii is buried, or a Goldau or golden valley, once near the Righi Mountain, is sent headlong down into a Swiss lake, a mass 100 feet deep, 2 miles long, and a fifth of a mile wide, containing four villages and 1,000 people, and covered with burning timber, ignited by the friction of the moving rocks and saturated with the steam of the vaporized subterranean waters.

The first movement that a plant makes is to back out of its seed case.[1] The root at once strikes for the center of the earth. If seeds are germinated upon a wheel revolving parallel to the surface of the earth, the roots will follow an oblique line that will slant more or less toward the earth, according as the wheel goes round faster or slower. Having thus commenced, the root lifts what is called the head or top of the plant into the air, either from the ground or out of its own body. This head consists of two or more leaves, which have no more resemblance to the true foliage of the tree—the third phenomenon to appear—than the tadpole has to the frog, as may be seen from figures D and E, page 982, specially selected to show extremes of divergence between the seed and the true leaves.

The tip of the root or radicle, as it is called, as soon as it protrudes from the seed coats begins to circumnutate or revolves and the whole growing part continues to do so as long as that root continues to grow. In winding its way downward the root insinuates rather than forces itself. The root of a sprouting bean will lift a weight of at least a quarter of a pound placed on top of it, but will make no impression upon a piece of tinfoil placed beneath it, though that foil is so thin that a little soft-wood stick with an end resembling the root tip will dent it if a weight of a quarter of an ounce be gently placed upon its upper end.[2] It seems impossible to conceive of any motion forcible enough to penetrate the soil without connecting with it the idea of a blow delivered against the material through which entrance is being made, but the conception is facilitated if, instead of looking on the root tip as an awl driven by blows from within, we regard it as an hydraulic press. The root cap, a delicate point, finding entrance in the porous soil, is enlarged by the formation of new cells laid on within the socket of the cap which holds the root proper, and it may be assumed that a pressure that will lift a quarter of a pound will squeeze the earth aside. In the case of a pumpkin, indeed, we shall find the formation of cells lifting 5,000 pounds, just as the flow of sap indicated a pressure of 4 or even 5 atmospheres. But there is still another conjecture that may be ventured, and that is a comparison of the sucking-in power of the root with that of the driven well sunk to a gravelly stratum. Such a well will eventually absorb the very fine particles among the gravel, and, the water being lifted out thus, creates a reservoir or pocket for itself.

To illustrate this, reference is made to the figures on page 931, proving that the muff of hairs is essentially the feeding part of the root. Let such a sprouting plant as is represented in those figures be carefully lifted and marked by some innoxious fluid into three parts, the lower one being divided into ten subsections, and then let the plant be placed in damp moss until its root has grown to three times its original length. It will be found that practically only the ten divisional marks have separated; in short, the root grows most between the cap and the top of muff, as is shown in the diagrams given in the cut on page 983.[3]

"We know that it is the part of the root just above the cap that grows the fastest, and it is certain that after the cap has been cut off the stump goes on growing at

[1] Professor Balfour in Ency. Brit. (p. 94, English edition), makes this statement. Professor Gray, in his review of Darwin's Movement in Plants, uses this language: "The radical with which the germination of decotyledonous seeds usually begins," p. 305-306 of vol. 1, Scientific Papers of Asa Gray.

[2] Power of Movements in Plants, pp. 69, 70.

[3] The figures and statements are taken from Mr. August Daguillon's Notions de Botanique, 2nd. ed., Paris, 1892. Van Tieghem stated in 1870 it had been found out that it was not the root cap or the spongioles that feed the plant.

such a rate that its length has often doubled in a day; nor does the removal of the cap prevent the part between the muff and the stump from bending if the plant has fairly started," says Darwin.[1] With a muff of hairs soaking up the water above the cap, it would seem that the cap would never be earth bound and its shaft would always have room to wriggle and thus to work the cap toward water, for which its scent is as keen as that of a hound for its prey. It is not mineral

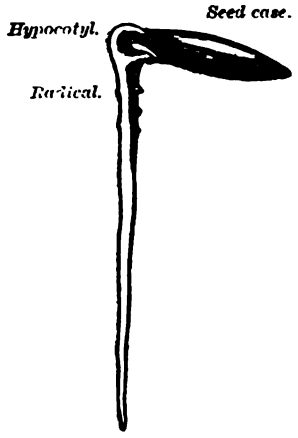


FIG. A.—Curcubita ovifera, germinating seed showing heel or peg holding down lower lip of seed coat. (Darwin, Power of Movement in Plants, p. 102.) If the lower lip of the seed coat is cut away, the seeds "come up" with tops boxed up in their cases, and are thus unable to act as chlorophyll plants.

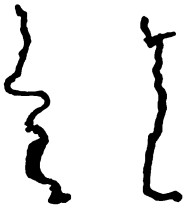

FIG. C.—Tracks left by tips of radical on smoked glass placed at angle of 70°. (Power of movement in plants, p. 99.)

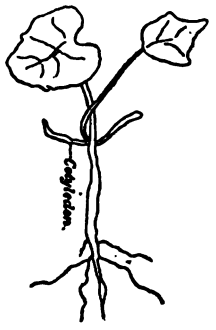

FIG. D.—Seedling of *Menisperinum canadense*. From Lubbock's Seedlings.

FIG. E.—Hakea acicularis (Australia). From Lubbock's Seedlings.

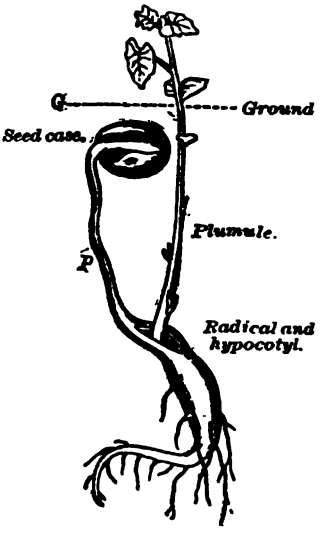

FIG. B.—Curcubita megarrhiza (Californica) (Gray); plant sprouting after the fall rains; about Christmas buries itself four or five inches in the ground, and is thus protected from the approaching cold of January (letter to Professor Gray, of Harvard); and in a few weeks the lower end of the sprout sent down by the seed is enlarged into a little tuber abounding in starch. Mr. Darwin thinks that this protects it from animals, but possibly the dry Californian summer has something to do with it. (Prof. Asa Gray.) Like figure A, this is a gourd, but there is no vestige of a peg nor is there any necessity for one.

nutriment, but water, that the cap seeks, and if it were necessary to explain the ramification of the lateral roots, it might be said that they are fostered by the shade and drainage of the foliage which has been produced by the taproot. It is thought that this point is well illustrated in the figures on page 984.[2]

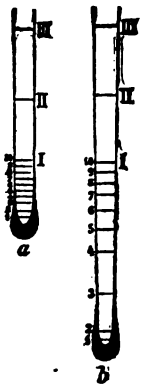
Thus endowed with machinery, the plant works. It is a part of the "blind economy" of nature, but it seems to throw itself into the struggle for the perfec-

[1] Power of Motion, pp. 542, 543.

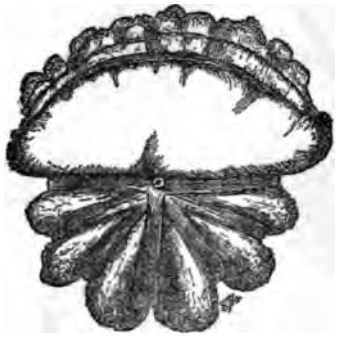
[2] Mr. Sargent, in Appleton's Popular Science, has given these cuts to illustrate the effect on roots of the drip of a watershed. November, 1890.

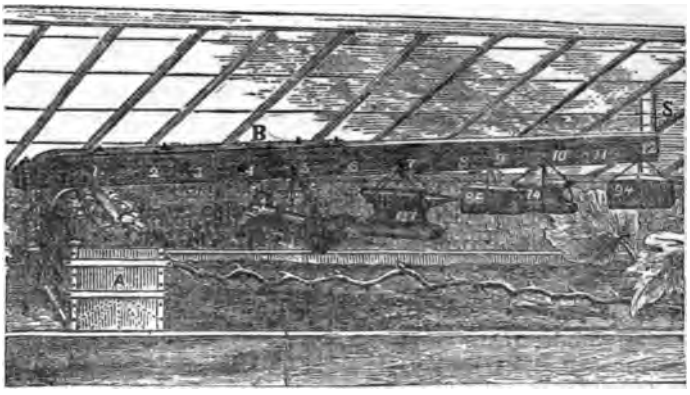
tion of its fruit with energy, though its only reward is to be the preservation of its kind. Some years ago[1] a pumpkin some 8 inches in diameter was imprisoned in a close-fitting box, but instead of a top of wood a network of iron bars was fitted over the upper surface of the fruit. Across this cage and resting on the iron bars was placed a beam 5 by 6 inches square and 9 feet long, subsequently strengthened by an iron plate 4 inches wide, half an inch thick, and 5 feet long.

In the course of the development of this fruit it lifted, on August 21, 60 pounds; August 27, 356 pounds; September 11, 1,100 pounds; September 30, 2,015 pounds;



The part of the root that elongates.





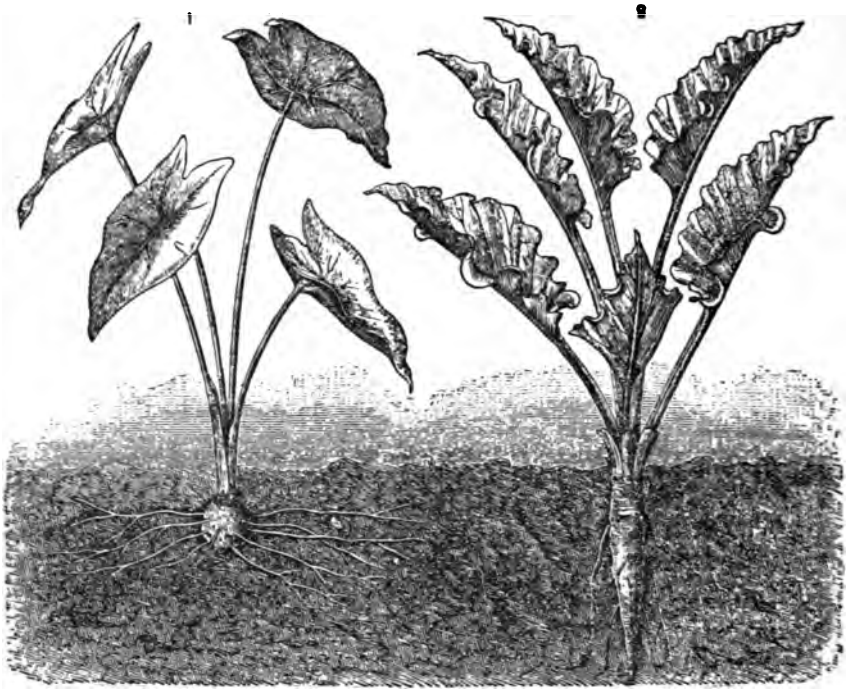
October 24, 4,120 pounds, and when, on the 31st, the lift had reached 5,000 pounds, the iron cage or network bent beneath the strain. The interior of the pumpkin was filled with fibrous tissue and the normal number of plump and apparently perfect seeds, though the pumpkin itself was malformed around the bars of its cage so as to be beyond recognition, the fruit having adapted itself to whatever space it could find as readily as though it had been a mass of caoutchouc. The lifting power, strange to say, was greatest at midnight. It is sometimes said

[1] Addresses before the Massachusetts Agricultural Societies, by President Clark, of the Massachusetts College, in 1874 and 1875.

that mushrooms will spring up in a night, but we know that mushrooms do not elaborate inorganic material into the fermenting matters upon which they feed. To do that requires time.

HUMAN INTERFERENCE AND "NATURAL SELECTION" IN THE VEGETABLE KINGDOM.

Professor Wiesner, of Vienna, does not believe in circumnutation; his experiments with plants tell him a different tale. He contends that their movement is caused by a leaning first to this and then to the opposite side, due to inequality in the force which is lifting up, or, in the case of the root, pushing down the growing mass, or even it may be caused by irregularity or unsymmetry of structure. This is substituting a mechanical view for the quite different one advanced by Darwin as an hypothesis. On the Darwinian theory of adaptation of a plant to accom-



Caladium, esculentum showing centrifugal watershed. Rhubarb, showing centripetal watershed.

plish its own inheritance, it must apply old wheels, springs, and pulleys to new conditions.[1] A spiral movement, then, if a regular movement, is not an accident, but an inheritance. The act of nodding around or circumnutating is a spontaneous act, which in psychology is called reflex. But in psychology a reflex act is a "nervous" act, and is generalized and called the faculty of "irritability." In vegetable physiology the nearest approach to a reflex act is a "turgescence," a swelling of the cell, or a number of cells, caused, it is said, by "osmosis." Turgescence has two directions, geotropic and heliotropic. Geotropism is the result when the plant bends toward or sinks its parts in the earth; heliotropism is when it rears its parts aloft. Geotropism may be called the effect of gravity, and heliotropism the effect of light. It is not the purpose on the present occasion to enter into the niceties of either

[1] On the Fertilization of Orchids by Insects, 1862, 2d Amer. ed.; revised 1892, pp. 283, 284.

of these isms, the literature of which is mostly in German, and has been largely the work since Hofmeister, of Sachs, and his botanical institute at the University of Würzburg. It is not to be wondered at that in the two countries of Europe—England and the South German States—where varied agriculture has flourished the best, we should find the best and most prolific investigations upon the dynamics of vegetation. It must be assumed then that roots are naturally geotropic and chlorophyllian leaves are naturally heliotropic. There is, therefore, strong evidence that plants show a reflex activity, that is to say, a spontaneous power within themselves to react upon their surroundings for their own good, and instead of agricultural instruction and inquiry confining themselves to the soil, they may busy themselves like the breeder of sheep and of race horses with the original habitat and the reflex idiosyncracies of the plant. Indeed it may

be said that Mr. Darwin emits a criticism from which it may be inferred that this has not always been done. "We experimented," said that observer, "on a variety of the common pea, the Yorkshire Hero, which has a much wrinkled, tough skin, too large for the seed leaves, so that out of thirty peas which had been soaked for twenty-four hours and then allowed to germinate on damp sand, the radical or germinating sprout of three, one-tenth of all, were unable to escape, and were crumpled up in a strange manner within the skin; four others were abruptly bent round the edges of the ruptured skin against which they had pressed. Such

abnormalities would probably never, or very rarely, occur with forms developed in a state of nature *and subjected to natural selection*."[1] Professor Trail, of London University, England, informed Dr. Francis Warner that by increasing the edible or "cellular" portion of the wild carrot, which is comparatively largely composed of fiber, the "cultivated root is much more liable to disease from attack of fungus, while fluids from the soil have to penetrate through a thicker layer of cellular tissue [or flesh] to the vascular bundles [or fibers] than in the case of the wild plant. The altered proportional growth of parenchyma [flesh] and the vascular bundles [fiber] *may be advantageous to the gardener, but is not advantageous to the plant*."[2] It is therefore proper to ask, "What is natural selection?"

The part of the plant which is most attractive to the insect, as well as to the human eye, is the flower. Yet lichens, mosses, and fungi are constantly taken as models by insects, and there is probably nothing in the vegetable kingdom that is not imitated by some animal form,[3] but the menteur à triple étage, the thrice-dyed liar of this description, is the African insect whose disproportionately broadened back bears the impress of a vivid green leaf with midrib and veins complete. On the other hand, plants have uses for insects. "The forms and colors of wild flowers," says Sir John Lubbock, an authority on the manner and customs of

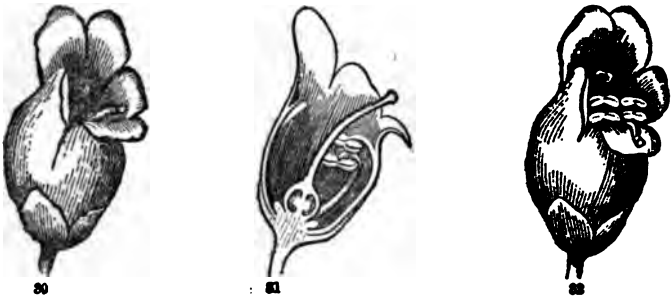

FIG. 30. Flower of Scrophularia nodosa, the first day. Fig. 31. Inside view of it, the front half cut away. The stigma is erect and fresh. Fig. 32. Flower as it appears on the second day. The anthers are erect and fresh, but the stigma, or rather the pistil, is practically dead unless it has been fertilized by the pollen of the anthers of some flower of Scrophularia, either by an insect or the wind bringing it to the stigma. [After Gray.]

insects, "are mainly owing to the unconscious selection exercised by insects, although no doubt the existence of a certain amount of coloring matter is, as we see in the autumn tints, in various fungi, seaweeds, etc., due to other causes." It will at once appear what an important bearing these facts would have in suggesting or proving an hypothesis that maintains that self-fertilization tends to produce weaklings in the vegetable kingdom, and that cross fertilization—that is, the fertilization of one flower by the pollen brought from another—is necessary to the production of a vigorous vegetable constitution.[4]

It has been shown how plants "sleep." It is the same with flowers. The dandelion is said to close at 5 p. m., the white water lily at 4, while other flowers, like the night-blooming cereus, open only in the cool of the evening, or, like the

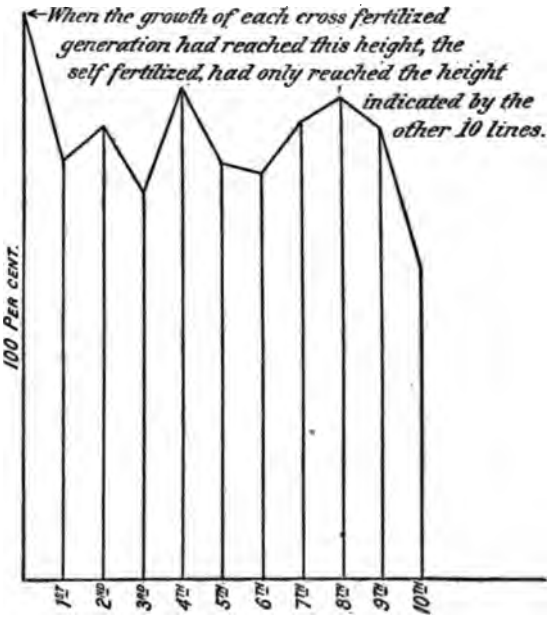
[3] British Wild Flowers Considered in Relation to Insects, London, 1890, by Sir John Lubbock,

[4] "It is hardly an exaggeration to say that nature tells us in the most emphatic manner that she abhors perpetual self-fertilization."—Fertilization of Orchids, last sentence in book. Cf. also chapter on Exogamy and Endogamy and their relation to incest in Starke's Primitive Family.

morning glory, in the freshness of breaking day. "I would venture to suggest," says Sir John Lubbock, "that the closing of flowers may have reference to the habits of insects, and I may observe, in support of my suggestion, that wind-fertilized flowers do not sleep."[1] Be this as it may, Mr. Darwin does not hesitate likewise to venture an assertion that "as plants are adapted by such diversified and effective means for cross fertilization, it may be inferred from that fact alone that they derive some great benefit from the process." In fact, such an inference is the positive or ethical import of the Darwinian hypothesis.[2]

Three of the tests made by Mr. Darwin as to the variation of plants under human manipulation are especially prominent, two of them, those on an exotic morning glory and on the pea, being pointed out by himself, and one, on corn (*Zea mais*), by Mr. Galton, who selects the results for statistical interpretation from a number of sets of observations. Mr. Darwin bred ten generations of plants of the morning glory, and as far as the vigor of generation is concerned the following diagram will show the results. The taller line indicates the height to which the plants grew which came from seeds produced by the fecundating matter of two different flowers on two different plants. The shorter lines indicates the height to which plants grew which came from seeds which were produced by one flower of a plant entirely within itself.



Before turning to another test, which had an entirely different suggestion, let us make a distinction about progenitors of the seeds experimented with. Let us call all seeds formed by the flower itself, whether composed of one or more pistils, an incestuous seed, formed by vegetable brothers and sisters, but when the seed is formed by the pistil or female portion of one flower when fecundated by the pollen from the anther of another flower (both flowers coming from sister or brother seeds), then let us call the seed formed by that kind of cross fertilization cousin seeds. It will be observed that the long line represents the vigor of the cousin seeds and the shorter ones the incestuous seeds. To show that there is not the slightest attempt to beg the question for the cousin seed by the mere ideas which words suggest, another Darwinian test is given, in which the incestuous seeds apparently turn the tables on the cousins. This is the experiment with a variety of the pea called the "Early Emperor" which had been self-fertilized for many generations:

	Cousin seeds (100 per cent).
	Incestuous seeds.

"There can be no doubt that the result would have been widely different," says

[1] British Wild Flowers, etc., p. 26.

[2] The Effects of Cross and Self Fertilization in the Vegetable Kingdom, p. 2.

Mr. Darwin,[1] "if any two varieties out of the numberless ones which exist had been crossed." But the element he lays particular stress upon is environment. He ascertained by crossing the ninth generation of morning glory cousins with pollen from a stranger family that he could produce plants as superior to the tenth generation (100 to 78) of cousins as that generation (100 to 77) was superior to the tenth incestuous generation. "The most important fact at which I have arrived," he says, "is that the mere act of crossing by itself does no good. The good depends on the individuals which are crossed differing slightly in constitution, owing to their progenitors having been subjected during several generations to slightly different conditions, or to what in our ignorance we call spontaneous variation. * * * This throws light on the origin of the two sexes and on their separation or union in the same individual, and lastly on the whole subject of hybridism, which is one of the greatest obstacles to the general acceptance and progress of the great principle of evolution."[2]

Still as between plants from cousin seeds and those from incestuous seeds the greater constitutional vigor is with the cousins. They not only grow higher, after getting well started, but they will withstand extremes of temperature better, the deadly pressure of competition in a crowded vegetable community, and even when they have not exceeded the plants from incestuous seeds in growth, when cut down they sprout and grow more vigorously. It is now necessary to close these remarks about heredity with the facts about plants grown from corn seeds, by Mr. Darwin, and sent to Mr. Galton for statistical arrangement, as before mentioned.

THE SYNTHETIC CHEMISTRY AND BIOLOGY.

Some explain the movements of plants by saying that the plant performs its movements in a mechanical manner as the compass needle follows the magnet, others that there is an act of willing perhaps, certainly a reflex or spontaneous act on the part of the plant, such as the winking of the eye when suddenly affected. In short, on one side it is claimed that the plant moves mechanically because its cells swell (turgesce) unequally, and on the other that the plant is endowed with "irritability." "When my father wrote our book upon the power

[1] Cross Fertilization, etc., p. 163. [2] Cross Fertilization, p. 27.

of movement in plants," says Mr. Francis Darwin,[1] "he adopted the conception of irritability, and the only trace that he was able to find of similar ideas was a passage from Sachs, in which that writer said: 'The living matter of plants is internally differentiated in such a way that the different parts are endowed with specific energies resembling those of the nerves (Sinnesnerven) of animals.'"[2] The nearest approach that science can make to living matter is a class of chemical compounds called the compounds of carbon[3] (or organic chemistry), which at one time were thought to be producible by living organisms alone. But this idea has been shown to be erroneous, for several of such compounds have been formed from inorganic substances without the intervention of the "life process," and these successes have changed the "new chemistry" of the sixties into a still newer chemistry to which the name "synthetic" is being given, as it is based on constructive rather than destructive analysis. In fact, beside the chemistry of oxygen and the oxides there is now the chemistry of the carbons, while hydrogen and nitrogen in the oxide forms of water or nitric acid have a leaning toward carbon that is peculiar to themselves, though it is going much too far to say that their combinations with carbon form "living matter of plants," a property which is generally spoken of as belonging particularly to "protoplasm."

The first result of synthetic chemistry was startling. Water was made out of two "airs." The apparatus by which this feat was accomplished in the hands of an Englishman, Cavendish, was not intricate. An open-mouthed glass jar, turned upside down, was filled with hydrogen, and then a candle and oxygen were introduced, the water formed collecting on the sides of the jar and dropping down. To a French chemist, however, belongs the honor of founding the synthetic chemistry. This gentleman, Monsieur M. Berthelot, succeeded in making acetylene by igniting carbon sticks in an atmosphere of hydrogen. In the following notice an attempt will be made to explain, with as few inaccuracies as possible, the ideas of M. Berthelot, who may be looked upon as doing for the chemistry of the carbon compounds or organic chemistry what M. Lavoisier did for the chemistry of the oxides or inorganic chemistry.

In "organic chemistry founded upon synthesis," there are eight fundamental types, eight types performing eight functions, eight functions here synthetically arranged in the order of their formation.

I. Hydrogenated carbons (acetylene CH, ethelene CH^2, etc.).
II. Oxidized hydrogenated carbons formed of carbon, hydrogen, oxygen.
  (*a*) Alcohols. Ordinary alcohol, for example.
  (*b*) Aldehydes. An alcohol from which two atoms of hydrogen have been taken, such as camphor.
  (*c*) Acids. An oxidized aldehyde, acetic acid.
  (*d*) Ethers. Ordinary ether, for example, formed from an alcohol by treatment with potassium, sodium, iodine, bromine, chlorine, or from (*b*) or (*c*).
III. Nitrified hydrogenated carbons formed of carbon, hydrogen, and nitrogen.
  (*a*) Alcalis. The union of ammonia with the alcohols or aldehydes.
  (*b*) Amides. The union of ammonia with the acids with separation of water, such as albumen.
IV. Compound metallic radicals formed by the reaction of the metals upon certain ethers, such as cacodyle composed of carbon, hydrogen, and arsenic.

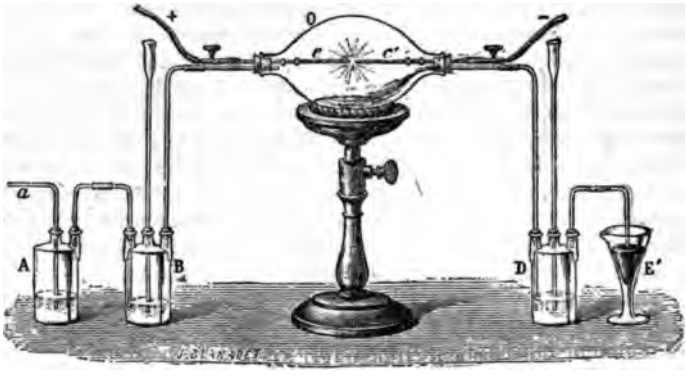
Of all these functions, two—the hydrogenated carbons and the oxidized hydrogenated carbons called alcohols—are of the greatest importance. These once obtained, it is easy to form the six other functions. These two, then, are the true foundation of organic chemistry. The hydrogenated carbons are formed by the action of the electric arc upon hydrogen and carbon as shown in the cut below.

[1] In his address on Curves made by Plants, at the meeting of the British Association for the Advancement of Science, at Cardiff.

[2] Sachs's Arbeiten, Vol. II, 1879, p. 282, as quoted by Mr. Francis Darwin in Republished (in French) Address by M. Richet, in Revue Scientifique, October 3, 1891.

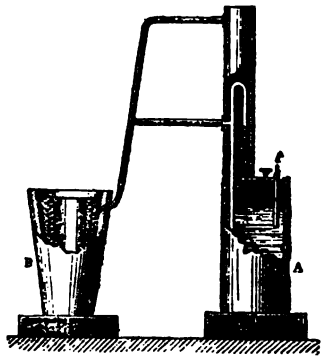
[3] Cf. Remsen's "An Introduction to the Study of the Compounds of Carbon" for the name.

Acetylene (CH) being thus produced, ethelene or "olefiant gas" (CH^2) is generated from it in the same way by certain precautions, and so on to formene or "marsh gas" (CH^4). Now, acetylene may be condensed into a liquid which is like, but is not, water. These products are called diacetylene, triacetylene ("benzine"), tetracetylene, or styrolene, which is formed by vegetables, etc., according as two, three, four, or more acetylene molecules unite to form the liquid.



The method of M. Berthelot in making acetylene one of the two bases of the chemistry of living substances.—Troost's Chemistry.

From the same property ammonia gas is used as a refrigerating agent. A quantity of water, having been saturated with ammonia gas, is heated in the cylinder A, and the gas is freed and passes over into the cool vessel B and liquefies, as shown in the illustration. Then the vessel C containing the water to be frozen into ice is placed in the vessel B and the cylinder A is surrounded with cold water. The liquid ammonia in B slowly changes back into a gas, which is again absorbed by the water in A, and, in doing so, makes things so cold in B, which it has left, as to freeze the pure water in C, which was the object to be effected by the operations.



Miniature ice machine.

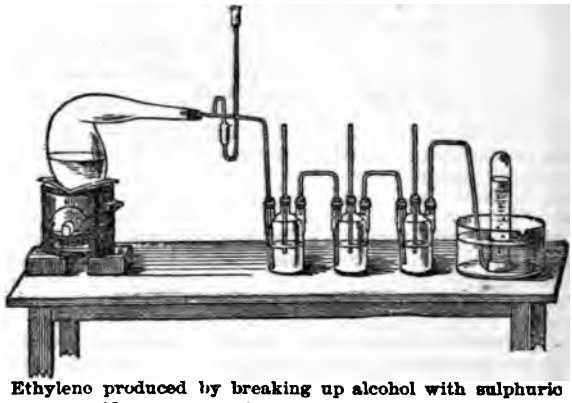
Why liquids should act thus in vaporizing is a very large subject, and it will suffice to say that "a great quantity of heat becomes latent during the formation of a gas;" yet to illustrate the curious effects produced, when common air has been so condensed as to be heard dropping in the condenser and so congealed as to resemble blanc mange (it "is a curious sight to see a cake of it well up in the middle as it changes back into air on being taken from the condenser") an account of the apparatus used in the process is given in Note A to this chapter. But let us pass to the oxidized hydrogenated carbons, and particularly the alcohols.

In the methodic presentation of the threefold or ternary compounds of carbon with hydrogen and oxygen the alcohols are of the greatest importance. Prepared by the means of the hydrogenated carbons, they, in turn, are used to fabricate the ethers, aldehydes acids, alcalis, and the rest. M. Berthelot so insists upon the chimie synthétique as opposed to the chimie analytique, that the difference must be illustrated. In a wine glass half filled with mercury let a tube filled with acetylene and hydrogen be introduced as shown in the view. Then let the tube be warmed and the result will be that "the organic" base acetylene (CH) will be hydrogenated and

become partly, in such an apparatus, ethylene (CH^2). This, like the illustration of the formation of acetylene, is ethelene formed by synthesis. Note on the other hand the production of ethelene by analysis. First about 50 metric grams of alcohol are poured into a cup surrounded by cold water, then about 300 grams of concentrated sulphuric acid is added, the whole being shaken to prevent breaking the glass. When the compound has cooled off it is run into a glass retort, as shown in the illustration, having some sand in the bottom. The alcohol under the influence of the sulphuric acid changes into ethylene and water, the first flowing off through the tube is washed in the first flask which contains potash to absorb carbonic and sulphurous acids passing along in company with the ethylene and again is acted on in the second flask which contains sulphuric acid which catches the ether while the ethylene passes on purified.

Now, if, as Dumas said, the discovery of the chemical principle of the alcohols is as important as the discovery of a new metal, it will be evident that the synthetic manner of forming them out of acetylene and its forms of benzine and marsh gas and the like will be of interest not only to temperance crusaders and to

Ethylene (CH_2) produced by warming acetylene (CH) with hydrogen (H) or "*Synthetic* chemistry."



Ethylene produced by breaking up alcohol with sulphuric acid (concentrated) or "*Analytic* chemistry."[1]

distillers, but to the public in general. Alcohols, says M. Berthelot, are divisible into five great classes:

Alcohols properly so called or primary alcohols.

Watered alcohols (alcools d'hydratation) or secondary alcohols.

Tertiary alcohols.

Phénols.

Alcohols having a mixed function (à fonction mixte).

These are subdivisible into orders, monotomic, diatomic, etc., according as the one or more molecules of water they contain is replaceable by an organic acid, and these orders are subdivisible into families, such as acetylic alcohols, benzenic alcohols, etc. We are here concerned with formation of a genuine alcohol. There is first the method of substitution, in which every hydrogenated carbon engenders an alcohol by substituting water for part of the hydrogen contained in marsh gas $CH^2(H^2)$ for example. In short, the carbon, before merely hydrogenated, is now hydrated by the addition of oxygen. But the work of water is still more emphatic in the making of an alcohol from a hydrogenated carbon by the method of addition. In the method of substitution half the hydrogen was oxidized, but in the method by addition the elements of water (hydrogen and oxygen) are simply

[1] Both these illustrations are taken from the Chemistry of M. Troost, professor at the Faculty of Sciences of Paris, eighth edition. Mr. Berthelot's book is a brief for the Chimie Synthetique, not a text-book.

added, but this is only possible with low grades of hydrogenation, such as acetylene (CH) or ethylene (CH_2). Insisting, then, irrespective of M. Berthelot, on the value of "substituting" and "adding" water, or the "elements of water" in the proportion in which water is formed, to the formation of the hydrocarbons or carbohydrates, known as cellulose, glucose, and cane sugar, and the other secretions of vegetable life, we pass to his conclusion générale:

The point of departure for the formation of organic matters is the same as that of the formation of mineral matters. We start out with carbon, hydrogen, oxygen, and nitrogen. With these and the mere play of the mineral forces we have formed twofold compounds of a fundamental nature and principally the hydrogenated carbons. They constitute the keystone of the whole edifice of organic chemistry. After having formed the hydrogenated carbons we have constructed, always starting out from realized facts and basing our work on methodical treatment and following general laws, a new class of compounds called alcohols, a threefold substance having no resemblance to anything in mineral chemistry and, moreover, formed here by the mere play of affinities. This synthesis gives to organic chemistry a definite basis. The alcohols in turn combine with the [organic] acids to form the ethers, a new class of artificial compounds, naturally produced as the odor of the greater number of fruits, aromatic and irritating qualities, seeds, such as in gaultheria and in mustard, and the waxes, such as beeswax. These same alcohols united to ammonia give rise to artificial alkalies, which, their laws being known, permits us to hope that at an early day we can reproduce artificially the vegetable alkalies, such as morphine, quinine, strychnine, nicotine, and other active principles in vegetation.

Again, if we manipulate the process a little we can oxidize the alcohols so as to form the aldehydes, a very singular group which contain the greater number of the naturally oxygenated essences, such as th. odor of mint and bitter almonds, ordinary camphor, etc., but to make these essences it is first necessary to realize the formations of the alcohols from which they are to be formed. A higher degree of oxidation of the alcohols engenders another class of compounds, the organic acids. A multitude of natural acids have been artificially formed from the alcohols, such as the acid of vinegar, of beer, of valerian; but when we come to the natural acids still more oxygenated, such as malic and tartaric, acids then we are unable as yet to produce by synthesis in our laboratories what nature produces in hers. From the acids come the ethers and the amides. The amides are compounds which are the result of the combination of acids with ammonia. To the study of the amides belongs undoubtedly the formation of all the natural nitrogenous principles which are not derived from the alcohols. Among the principles which have been artificially created by the synthetic chemistry it will suffice to mention urea, one of the most important excretions of the higher animals, taurine matter contained in the bile, gelatin, sugar, leucin, and hippuric acid. These general groups of organic compounds comprehend the volatile matters and the bodies that may be formed by them. What has been effected in the artificial formation of substances formed in living bodies is only the first stage of organic chemistry. Fibrine and woody fiber and the sugared and albuminous matters dissolved in the liquids which bathe these tissues are still without the sphere of the chemistry by synthesis. *The discovery of the way in which these substances may be made artificially will be the second stage of the progress of biologic chemistry.*

A review of the material sources of vegetation tends to affirm the old idea that plants are creatures of the atmosphere. "Man," said the Chemist Dumas, "is condensed air," and if that assertion can be made with some degree of probability of man, it is still more probably true of the food of man or of the food of the animals upon which man feeds. It has been already remarked on this occasion that nature, unlike the synthetic chemistry, starts with compounds. She takes an oxide of carbon, the deadly carbonic-acid gas, and it is broken up into its elements by the mechanism of the leaf worked by the sunbeams. Neglecting the free nitrogen of the air, she for some inexplicable reason feeds it to the plant in the form of nitric acid, another deadly poison, through the mechanism of a fungus microbe which works under cover of the soil. Hydrogen alone she is compelled to furnish to the plant in a compound form, and as for oxygen the plant in daylight both discards and absorbs it at the same time. These substances are not costly. The air is composed of oxygen and nitrogen and there is enough carbonic acid in it to sup-

ply many times over the needs of terrestrial vegetation, while water abounds except in vast interior basins like the American Desert, the Sahara, and the interior of Australia. Can science aid agriculture to appropriate these elements regularly and systematically? That is a problem of agricultural economy. What chemicals shall be poured into the soil? That is a problem of agricultural hygiene. Both are branches of practical agricultural chemistry.

The synthetic chemistry teaches us that the "elements" of biologic chemistry are not the sixty or seventy "elements" of the text-books, and spectrum analysis suggests the possibility that those sixty or seventy elements may be compounds, as M. Berthelot has shown the organic elements to be. The word element may therefore be a mere relative expression, and in any starting out it is possible to think that a table of elements may be drawn up to suit the convenience of the voyager. It therefore seems not unworthy of consideration to begin agricultural chemistry with a study of water, nitrification, the assimilation of carbon from carbonic acid, and the formation of the hydrogenated and hydrated carbons within the plant.

Among the many questions by which the brightest intellects which have busied themselves with agricultural chemistry are cowed is one which may be formulated in these words: Can I feed pigs on corn so that at six months old they will weigh 300 pounds? If so, what breed of pigs, on what kind of corn? This is a practical question, for a true answer to it would have enabled the possessor of the secret to have enriched himself at the expense of his neighbors who had not been sharp enough to obtain it. But to look upon public institutions as purveyors of money-making information for the practical inquirer is no more respectable than for a woman under the poor laws of England to regard herself as an heiress because she had a claim upon the parish for each of her five illegitimate children.

The farmers of western Europe, finding that the many agricultural colleges of their respective governments were incapable of telling each one how to get ahead of his neighbors in raising pigs, have begun the formation of trusts or "syndicates." So powerful are these organizations becoming that they merit attention and study. In the portion of this chapter which immediately follows these institutions are described after a brief review of the history of the agricultural population of Europe.

PART II.—SOCIOLOGICAL CONCEPTIONS.[1]

The growth of cities in population is frequently regarded as somehow connected with the present depression in agriculture (which it is the purpose of agricultural education to remove), though it might be supposed that the increase in the number of city dwellers would infallibly increase the price of the productions of the farmer. Such is not the case; and before engaging in the study of cooperation among producers of food and other raw material, the object of this portion of the chapter, it may be well to inquire under what conditions of birth rate, personal aspirations, and human faculties the people of the open country emigrate to the city, since, as Bacon says, ignorance of the cause masks the effect.

The great desire to live in cities which now animates the people of the nineteenth century is not peculiar to them. Before Rome had policed the Mediterranean Sea the little city-states that fringed its shores and occupied its islands were accustomed to store their productions and plunder in citadels built, as at Athens and Corinth, upon a precipitous rock; and subsequently, as their wealth and commerce increased, to inclose the citadel with wide-extending walls, as many centuries later the colonists in America built their blockhouse and then surrounded it with a stockade. But protection of life and property is not the incentive that is now

[1] It is to be remarked that the second congress (1896) of cooperation, composed of men of high political and social standing, demanded that every public-school child should be compelled to study cooperation in all agricultural and industrial schools for pupils over 15.

causing the cities to grow, for the present movement of the population is a · versal influence experienced by a very large number of individuals. These nom impulses are inherent in human nature, and the restlessness they produce in s ety at large has not failed to receive attention from government after each na has passed from the pastoral or wandering condition to one of fixed territo confines or nationality, or, in other words, become a state, or, in the languag the Greeks, a city.

COLONIZATION.

The most vigorous manner in which a society is relieved of its restless or agreeable elements is by an emigration which is induced by the hope of fortun of escaping the control of too rigorous laws. The revocation of the Edict of Na sent 400,000 useful merchants and artisans forth from France, and the possibili of acquiring wealth in the West Indies and on the Spanish Main relieved Spai many thousands of adventurers and nobles for whom she had no use after expulsion of the Moors. The interference with the Puritan form of worshi the English Government peopled New England, and the defeat of "King Church party" by the Presbyterians under Cromwell greatly swelled the pop tion of Virginia. The devastation of the Palatinate, one of the war measure Louis XIV, and the famine in Ireland, due to an exclusive reliance upon a sin crop, caused thousands to leave their native land for one holding out promise a more successful existence.

Another method of relieving society of an uncongenial element is that of tr portation. This, however, is far different from the natural emigration refe to above, since government seizes the person of the emigrant and sends him of the country either as a criminal or an insurrectionist. Tasmania was m years ago the penal colony of England, and France exported her criminal men women to the New World, as is graphically told in the romance of Manon Lesc by the Abbe Prevost, who probably saw the occurrences which he makes his h ine experience. Cæsar relieved Rome, "that den of robbers,"[1] of 80,000 of proletariate by transporting them beyond the Italian seas, and in ancient Gre the expatriation of a group of obstinate citizens was frequently and conscio made the remedy of relieving a political crisis, in order to serve, to use the guage of Curtius, "as a blood-letting in times of local feverish excitement."

In all this, let it be remarked, there is something of preconcertion or coo nation, and the movement is conceived to have taken place in the manner acc ing to which we fancy to ourselves the Aryans moving through the passes of Himalayas or the Helvetii, in Cæsar's account, moving into Gaul. It is the m we see; but to see the individual actors, to separate out an idea of the swee the movement, we must study the emigration from the Atlantic coast across Alleghenies. The Spaniards founded cities in America and dwelt in them; French established a line of trading posts from Quebec to New Orleans; but English have conquered the country, and in it the English language and the c mon law prevails.

ORGANIZATION OF THE PEOPLE.

Nevertheless, during antiquity and throughout the middle ages all men were at liberty to go where they pleased in pursuit of happiness. In the republic ancient Greece and Rome the State, or, as it was called, the "city," was concei as one separate class of inhabitants, called citizens, relieved from all private and all money-getting employments; "for it clearly follows," says Aristotle, "t

[1] Mommsen, Vol. IV, pp. 596, 598: "From the whole compass of the widespread empire pe flocked to Rome for speculation, for debauchery, for intrigue, for accomplishment in crim even for the purpose of hiding there from the eye of the law." If we try to conceive a Lon with the slave population of a former New Orleans, with the police of a modern Constantino the nonindustrial character of modern Rome, and the barricades and street riots of Paris in we shall acquire an approximate idea of the republican glory of ancient Rome.

in the State which is best governed the citizens who are absolutely and not merely relatively just men must not lead the life of mechanics or tradesmen, for such a life is ignoble and inimical to virtue; neither must they be farmers, since leisure is necessary both for the development of virtue and the performance of political duties."[1] "Government," says Mr. Edmund Burke in his Reflection on the French Revolution, evidently following Aristotle, "is not based on natural rights, but is to provide for human wants, and society requires not only that the passions of individuals should be subjected, but in the mass and body, as well as in the individuals, the inclinations of men should frequently be thwarted, their will controlled, and their passions brought into subjugation."

There have been three systems by which this subjugation has been attempted in European history, called, respectively, slavery, serfdom, and education. Upon each of these it is excusable to dwell for a moment in order to bring them into proper light, as two of them, slavery and serfdom, have signally failed to accomplish their purpose, and are matters of antiquarian interest.

SLAVERY.

"If a future historian," says M. Fustel de Coulange, "some centuries hence should attempt to relate the history of our civilization, it would be particularly necessary for him to study many things besides the life of the rural districts; but for the life of the European peoples existing between the Roman Republic and the sixteenth century, the study of their country life is sufficient." On the country estate was transacted the far larger part of the work, and there were elaborated both the wealth and the power of the community. It was in the interior of the country estate that men were brought together, and there the liberties and the restrictions belonging to each class were most marked, their inequalities exhibited, and their agreements and differences illuminated. To illustrate one of the inequalities thus announced by M. Fustel de Coulange, it is sufficient to say that Roman society had what it called a slave, or thing (res). This res was defined legally as one who is controlled by another, as property over which the master had the right of life or death, of loaning, pawning, or whipping. It is evident how differently a noncriminal white person is regarded at the present day. It is also evident that as all the slave earned was his master's, he would not be unduly excited by the spirit of acquisition. During the time of the first Roman emperors many of these rural slave persons were chained in gangs (vinctii). Thus the slave not only lacked liberty, but personality. This loss of personality was the especial vice of the system, for, notwithstanding the possibilities of cruelty, it is safe to say that the orderly slave was kindly treated.[2]

The numerical proportion of this rural slave population (many of whom were degenerated freemen) to the whole rural population is unknown. In Attica, containing the city of Athens, out of 500,000 people about 400,000 were neither citizens nor the wives or children of citizens.

SERFDOM.

But from the very trend of civilization even during the days of the Roman Empire a beginning was made to ameliorate the condition of the slave. The effort was in the nature of an appeal to the instinct in man which leads him to try

[1] Politics, "The governing classes," p. 221, vol. 1, of Jewett's translation. Grote interprets this in this way: The whole territory of the State belongs to them and is tilled by independent cultivators, by whom the produce is made over and apportioned under certain restrictions. Of course it will be understood that the politics is a theory about a State existing under exceedingly antiquated conditions.

[2] L'domaine rural chez les romains, Revue des Deux Mondes, September, 1886, also in part Hist. des Institutions Politiques de l'Ancienne France, L'Alleu et le Domaine Rural, Chap. I.

to take care of himself if compelled to. Some slaves were given plots of land to t for themselves. The master was thus freed from the necessity of providing f the slave's support, and could grasp as much as prudence or as little as generosi might suggest; but the first determined step in the way of enfranchisement w the enregistering these "cabined slaves" and their families as servi adscripti f the purpose of public taxation. Finally the State became strong enough to forb the master to sell the servus adscriptus unless the ground he tilled and his h were included as a part of the same transaction. It can not be said that the dai life of the slave was softer; probably, says M. Fustel de Coulange, it was hard for him, considering the slender resources he had at his command to struggle f existence. But he began to have a soul; he had a home from which, it is tru he might not move, but from which it is also true he could not legally moved. He had a wife and children; he had cares to worry him; success or defe to elevate or depress him, and he became acquainted with the great factors industrial life.

The germ of serfdom as a modification of slavery was merely sown by t Romans. It was nourished and propagated by the Germanic tribes that overr the Roman Empire. The Roman cabined serf was servus adscriptus—a sla inscribed on the tax lists; the feudal serf became fully ascriptitius glebae, o having a holding. As the northern tribes settled down, the maxim "no land wit out its lord"[1] policed the territory to which the serf was attached until the grow of cities, the Reformation, and the French Revolution swept the system out existence. The system of serfdom has been commented upon in this languag "To live and die as a serf upon the soil where one is born is the life of a pla which, while nourishing itself, is plundered of its fruit by its owner;" neverth less it may be added it is better than to be the mere talking tool, "the instr mentum vocale"[2] of the Roman country estate.

EDUCATION.

At the close of the period called the Reformation the peoples whom that mov ment deeply touched seem to have specialized their energies. The French ha won for themselves the European preeminence in art and literature, the Germa have cultivated philosophy both as religion and natural defense, and the Engli have thrown themselves into commerce and colonization. But even before th Reformation the people of England seem to have manifested a talent for person freedom as eventually expressed in the law of Habeas Corpus and the Bill Rights, only equaled by the Hellenic talent for form in art and literature and th Roman talent for centralization. Long before the expiration of the middle ag the courts held the serf to be a freeman against everybody but the owner of th land he was "ascribed to,"[3] and by the criminal or State law[4] he was on a perfe equality, as far as responsibility is concerned, with anybody in the land. H could appeal to the itinerant judge, whether "in eyre" or at "nisi prius," an place himself upon "his country" when he was claimed as a serf. It seems impo sible to separate the growth of personal freedom from the practice of the courts Westminster and the representation of the serf in the transaction of the busine

[1] Charles the Bald, of France, in 847 ordered each of his subjects to choose a lord, and the pr prietors of free lands offered their lands to a great lord, just as the States relinquished a part their powers to form a Federal Government.

[2] The elder Cato's brutal remark.

[3] Pollock, Land Laws, third edition, p. 61.

[4] The criminal law of England was a State monopoly long before it became so on the Con nent. Thus the court of King's bench, the highest of the three courts of law (King's benc common pleas, and exchequer) had a "Crown side," which took cognizance of all crimir causes, and the "plea side," which took cognizance of all civil causes except those of real (lan property (court of common pleas) and "revenue" (court of exchequer).

of the little local baronial court;[1] nor is it wide of the mark to regard the principle of the feudal system in England to be an effort to keep the land under cultivation, on the Aristotelian maxim of a division of labor between a class who are to work and not think and a class who are to think and fight but not otherwise to work.[2] In England the State in the beginning being an agricultural community, the organization of the people was effected by allowing the landlord certain rights upon the agriculturist as pay for his policing the manor over which he presided. With such a theory and the common law to invigorate and support it, the troubles which characterized the French Revolution culminated in England nearly two centuries before they did on the other side of the channel; but the political movement for personal liberty, "the rights of man," was in England masked under the name of theology and not under that of the "law of nature." There is no English law repealing serfdom such as that passed in France on the evening of August 4, 1789, nor any cabinet order like that of Prussia in 1808. Serfdom in England died out of pure inanition, and the last that was ever heard of it was a stray case during the reign of James I (1618).[3] In the process of this decay, which seems to have been particularly rapid during the disarming of the feudal barons by Henry VII, many persons were thrown upon the country, and to reduce the restlessness of the population the famous act of the fifth year of Elizabeth (1563) was passed, under the title of the statute of apprentices, though Mr. Froude claims that the act of the twenty-seventh year of Henry VIII (1536), drawn by that monarch with his own hand, was the first compulsory education law, for such that historian claims it to be.[4]

The seizure of the English monasteries by Henry VIII was based, in history at least, upon the plea that the funds which had accumulated in the hands of the religious corporations had not been given for the private use of the church, but for the poor and their instruction. But the money obtained in this way seems to have been appropriated somewhat after the manner described by Edmund Burke in these terms: "The monarch having sucked the blood of his prey threw the carcass to the jackals in waiting." Nevertheless about 250 "grammar" (i. e., Latin) schools were established for the education of that middle class or gentry which ruled England for the next three hundred years. Perhaps instead

[1] Cf. the title of the legislature of Massachusetts, to wit, "The general court of Massachusetts;" also the functions of the French Parliaments.

[2] Vinegradoff, Villanage in England, p. 158, for instance, as a basis for such a judgment; also Glasson, introduction to tome 4: Feodalite; and Aristotle's Politics, bk. 7, sec. 8. C. Ellis Stevens (in Sources of United States Constitution, a British work) calls attention to Taylor's "admirable condensation of the growth of the connection of the State with the local courts." In the course of the assessment and collection of the revenue, which was the chief work of the curia regis as a financial body, local disputes so constantly arose that it became necessary to send detachments of justices to adjust the business of the exchequer in each shire. As early as the reign of Henry I (1100 to 1135, say half a century after the conquest), officers of the exchequer were frequently sent through the country to assess the revenue; and in the reign of his grandson this custom was enforced with systematic regularity. The justices while thus engaged in provincial business sat in the shire moots where judicial work soon followed in the path of their official duties. In 1176 the Kingdom was divided into six circuits, to each of which were assigned three justices, who now for the first time were given in the "Pipe Rolls" the name of Justitiarii Itinerantes. After several intermediate changes in the number of the circuits it was at last provided by Magna Charta that two justices should be sent four times each year into each shire to take the assizes of novel disseizin, mort d'ancester (both real estate cases), and darrein presentment (which was ecclesiastic), the provincial visitations of the justices. (Taylor, Origin and Growth of the English Constitution.)

[3] Excepting Somersett's case, in which Lord Mansfield, 1760, delivered himself to this effect: "What ground is there for saying that the status of slavery is now recognized by the law of England? Villanage has long ceased to exist in England. [It had been argued that no statute had abolished the status of villanage.] The air of England has long been too pure for a slave, and every man is free who breathes it. Quamvis ille niger, quamvis tu candidus esses—Let the negro be discharged."

[4] Froude, History England (Tudor Period), vol. 1, pp. 87 and 89 (N. Y. ed.).

of the middle class it should be called the grammar or Latin school educa class, for through the aid of the endowments children of the laboring class w constantly fitted to pass into that of the directive class. Thus was institute process of natural selection. Any "gentleman" or member of the middle cl might become a nobleman. The youngest son of a noble was but a gentlem but the grandson of a nobleman yielded precedence to a newly made knight, a the dignity of knighthood was within the reach of any man who could by d gence and thrift realize a good estate or could attract notice by his valor in a b tle or a siege. There were untitled men well known to be descended from Norm knights who had broken the Saxon ranks at Hastings and had as crusaders sca the walls of Jerusalem, yet they bore no distinctive epithet other than that of squ and with no civil privileges beyond those enjoyed by every farmer and shopkeep The yeoman was not inclined to murmur at dignities to which his own child might rise. The grandee was not inclined to insult a class into which his o children must descend.[1] The key to success in England was personal abil either in battle or industry; but while providing schools for the children of educated class and for the bright-minded children of the poor class, the educat of the residuum or lower limit of the population was provided for by training manual labor. The theory was, in the language of Lord Derby,[2] that whene any youth, however poor, had shown really exceptional ability, he might enabled by some moderate pecuniary help afforded by some scholarship to go the classical school. Thus the State, through private endowment, segregated the bright intellects, just as before the Reformation they were picked out by monks and permitted by the lord of the manor, on the payment of a fee to him, desert the fields for the monastery.[3]

The next nation to consider the education of the emancipated serf was Fran In 1789 the French made the greatest effort ever made by a people to cut its h tory in twain, and they neglected nothing to render themselves unrecognizal "But I have always thought," continues M. De Tocqueville,[4] "that they w very much less successful in this singular enterprise than was fancied by oth or by themselves." Be this as it may, the whole system was swept away i single day and 150,000 villains or serfs, in the middle age sense of the word, w freed and as many nobles and nearly as many priests (130,000), who togeth owned three-fourths of the land, were deprived of their means of support for 25,000,000 who alone had paid the taxes (the nobleman and priest not being t ables) as well as the manorial dues, were liberated from the necessity of, amc other "seignorial rights," working fifty-two, more or fewer, days in the year their lord (corvée), of paying on the average one-sixth of the value of their hc ings when they transferred them to another (lods et vents), and of baking th bread and grinding their corn at the lord's oven and mill (banalités).

To educate the children of these emancipated agriculturists was the probl that the French revolutionists could not solve. Idealogues, as Napoleon cal

them, schemes were not wanting. What was wanting were teachers who were free from the habits of mind calculated to reproduce the past from which, as M. de Tocqueville says, the revolutionists so desired to free themselves, and with themselves their country. Wild schemes were proposed, such as removing children of 6 years of age from their parents, as was done in ancient Sparta, and placing them in "houses of equality," so that all might receive the same education until their twelfth year.[1] Another proposition still more absurd was to modify the French language in such a way as to make it more in keeping with the "language of liberty." The laws of the first French Republic regarding public education were of no avail, nor did the first empire, its successor, when establishing the system of education called the University of France, pay the least attention to the education of the common people, whom the Emperor probably deemed a nation of barbarians, to be civilized by the conscription,[2] as Henry VIII would educate them, by apprenticeship.

The third nation to adopt a system of education as a method of social control and pliability was Prussia. Her second and third kings modified the system of Leibeigenschaft (literally "personal property") into Erdunterthänigkeit (serf to the soil) and endeavored by cabinet orders in 1738 and 1749 to prevent the use of the whip upon the person of the agricultural peasants in order to stimulate their industry. The condition of the Prussian peasants may be expressed in the language of one who says that they were contented, "The peasant always belongs to somebody."[3]

In 1807, after the complete overthow of Prussia and the treaty of Tilsit, the minister Hardenberg was ordered by the King to draft a plan for the reconstruction of the Prussian State. In Hardenberg's plan it is laid down that the abolition of serfdom must be decreed briefly and immediately, and the laws which prevented the peasant from passing out of the peasant class and restricted office-holding to the nobility and relieved that body of taxation must be repealed.[4] Hardenberg being driven from office by Napoleon, the edict of emancipation was promulgated five days after Stein became minister, though not fully consummated until, to use Stein's language, "Chancellor Hardenberg's love of innovation led him in 1811 to transform the relations of the landlord and peasant class, in which I (Stein) had no share." But though Hardenberg's love of innovation induced him to make some of the late serfs small proprietors at the expense of the nobility, it was Stein who, seeing the effect of the religious and patriotic spirit which inspired the resistance of the Spanish peasants to Napoleon,[5] adopted the idea set forth in Fichte's address on the necessity of national and religious education of the people—the conception by them of the nation as the embodiment of the will of God—and armed with this idea he started the war of liberation. This idea, being successful in freeing Germany, survived and became more and more the idea of the Prussian Government—the idea which must guide in preparing for national defense.

INDIVIDUAL INSTINCTS AND SOCIAL UNITY.

In the preceding matter several facts have been brought into relation in order to illustrate the manner in which the European world at different epochs of its history has sought to secure the permanency of the social institutions peculiar to

the epoch. As far as the rural, and therefore very much the larger, part of the population is concerned, we have found that the Roman villa was the center of the agricultural life, then the baronial or manorial hall, modified in England by the administration of itinerant courts, and finally, either compulsory apprenticeship or school attendance. In the following section it is intended in the same brief manner to examine into certain impulses in human nature which may be supposed to be a source of constant danger to any social system which, through its government, strives to perpetuate itself by the exertion of the powers which have been conferred upon that government for the purpose.

It is evident to those who consider themselves authorized by experimental study to speak of the emotions experienced by the child[1] that the first feelings that it manifests are expressions of wonder and fear. These emotions are the natural instruments of its future intellectual growth, and at an early period of its subsequent mental development it is never so contented as when assured of security by association with its fellows and amused by a constant change in the objects presented to its senses. The love for spectacular amusements, of engaging in games of chance other than those played with nature, and for bestowing and receiving praise does not interest us here, as our object is to inquire what motive may be supposed to induce an otherwise contented man to seek centers of quick exchange and rapid circulation of money.

It would be difficult to find a business that as a business requires greater sagacity and physical exertion and withal more dependent on the element called luck than the business of farming.[2] Before the invention of marine insurance probably the merchant's ventures were as hazardous if not more hazardous than those of the farmer, but insurance has not taken risks on the probabilities of the agricultural weather during six months of the year, of the destruction of the crop by injurious insects, or of profits which are dependent upon conditions that will happen between the time the crop is planted and its harvest.[3] All these risks the farmer is compelled to take if he enters the world of competition, and unless he have a very deep insight into a futurity that is constantly becoming more ambiguous by competition, it will too frequently happen that his fertilizing material and his labor are expended in vain. Such, in general, seems to be the difficulty, especially in cultivating nonvirgin soil which requires manure, and the farmer or the farmer's son, finding conditions at home nonremunerative in an epoch of constantly increasing desires, at first gladly seeks to place himself under the directive power of those who employ labor in cities and manufacturing towns, where he thinks himself assured of remuneration and of relief from care, and perhaps of a "future."[4]

The facts which follow will probably sufficiently illustrate these remarks. The figures about to be given are for 34 cities of the Kingdom of Bavaria at the date of 1871. The cities range from 3,000 to 240,000, and the people in them, all of

---

[1] Dr. Preyer, for instance.

[2] "Back to the land!" is a cry to which in former days I have been little disposed to listen. Nearly twenty years ago (1870) close intimacy with the conditions, social and economic, of rural life have taught me that success in agriculture, even on a small scale, demands qualities of head and hand and heart which, to say the least, it is quite idle to expect from a merely miscellaneous company of the loafers and slummers and labor failures of town life. It is too often forgotten by the glib land reformers of our city debating clubs that the efficient agricultural laborer is not in reality the dull chaw-bacon sort of person shown in a comic illustrated paper, but one of the most highly skilled of English workmen. To expect, therefore, that the town laborer who has failed can readily be transformed into the rural laborer who will succeed is to expect miracles.—The Land and the Laborers, Rev. Charles W. Stubbs, M. A., London, 1893, Preface.

[3] In order to promote habits of thrift and economy, the Federal Government of Switzerland distributes yearly a sum of £4,000 ($20,000) among those farmers who insure their crops against hailstorms.—M. G. Mulhall on Swiss Agriculture, Report of Irish Recess Commission.

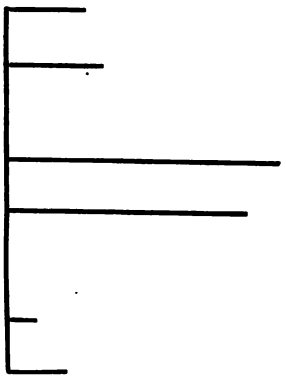
[4] In the London market, from 1872 to 1893, wheat fell 47 per cent, barley 30 per cent, oats 14 per cent, and in Prussia rye fell 13.3 per cent.

whom were born in Bavaria, were 622,988, against 4,740,185 persons born in the entire Kingdom. In other words, there were 622,988 city dwellers in the 34 cities who were born in Bavaria and 4,117,197 persons who were also born in Bavaria but who continued to live in the country. We may now arrange certain facts regarding this city and rural population in the following form:[1]

	Persons.
1. Showing the place of birth of the city population (622,988):	
In every 100 persons living in one of the 34 cities there were—	
(*a*) Born in some one of the 34 cities	57
(*b*) Born in the country	43
2. Showing the migration from the cities as far as relates to birth:	
In every 100 persons born in one of the 34 cities there were—	
(*a*) Living in city in which born	76.4
(*b*) Living in another Bavarian city than in which born	11.3
(*c*) Living in the country or had gone out of the Kingdom	12.3
3. In every 100 persons dwelling in the 34 cities there were not born within the boundaries of Bavaria	6

Thus it will be seen that only little more than half of the 622,988 persons in the 34 cities of Bavaria were born in a city; but this is far from expressing the exact character of the movement from the country to the city. Let us take a country like France, where the birth rate is stationary. In every 100 persons in the city of Paris on one side and all France, including Paris, on the other we find that there were—

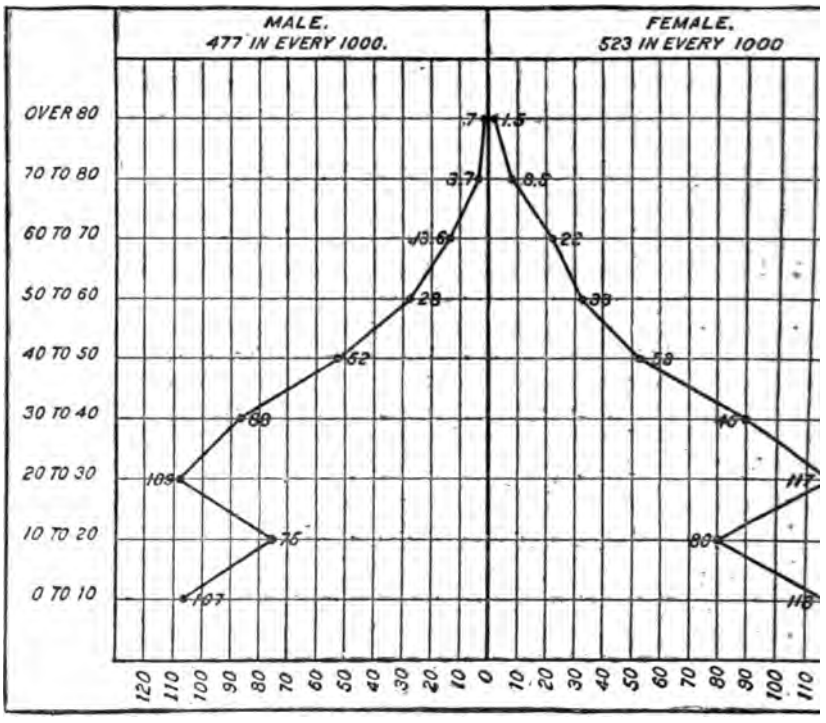
Of children up to 5 years in:	
City of Paris	20
Republic of France	26.7
Of adults from 15 to 60 years in:	
Paris	72.3
France	61
Of persons over 60 years in:	
Paris	7.7
France	12.3



It is immediately apparent how little impeded city life is with the very young or very old. We shudder at the atrocity of the Roman who "exposed" his child; but city life accomplishes the same result by another process, as will now appear. Observe the following diagram. The spaces between the lines that run across the page represent intervals of ten years. The lines that run up and down the page represent an increase or decrease of 10 persons in every 1,000 of the whole population of the city of Berlin accordingly as the line moves away from or toward the vertical heavy line in the middle of the diagram. Observe also that the starting dot and the dot at 20 on both sides the heavy line—that is, for both men and women—are almost in a vertical line. But see how pinched the diagram is at the intervening ten-years dot. These are years of great mortality for children, even of country parents. On both sides of the culminating point of youthful vigor, the age of 20, both for the men and women side of the diagram, the movement of the line shows how attractive to the young man and woman is the life of the city.

[1] The figures are taken from Dr. George Hansen's Drei Bevölkerungsstufen, who quotes them from the census. The writer is responsible for the computations and arrangement.

*Pyramid showing the great excess of men and women between the ages of 2(
30 in the city of Berlin in 1880, and the excess of women over men.*

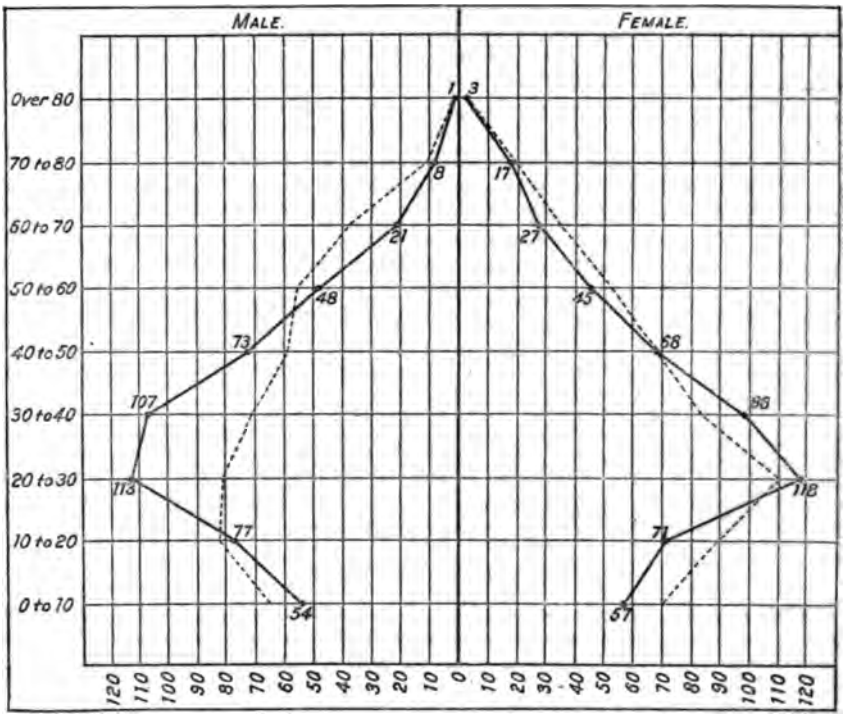


To verify the foregoing interpretation of the diagram for Berlin, let us con the statistics for the large city of Leipzig, remarking, as we do so, how m children over 5 years come into the city, and also the in-rush of those about age of 20. The sum of the two "total columns" equals 100, likewise also sum of the two "Male" columns.

Of the age of—	Of every 100 children living in Leipzig—					
	There were born there.			There were born elsew		
	Male.	Female.	Total.	Male.	Female.	To
0 to 5	86.5	86.2	86.4	13.4	13.8	
5 to 10	71.3	70.4	70.8	28.6	29.6	
10 to 15	57.5	59.7	58.6	42.4	40.3	
15 to 20	30	32.5	30.2	72	67.5	
20 to 25	14.6	25.7	20.1	85.4	74.3	
25 to 30	16.5	24.5	20.5	83.5	75.5	
30 to 35	19.3	25.4	22.3	80.7	74.6	
35 to 40	17.9	24.2	21	82.4	75.8	
Total 0 to 90	33.9	38.8	36.4	66.1	61.1	

Finally, to call attention to the effect that a demand for unskilled employment at a center has upon the population of the country districts or other centers, the following diagram prepared for M. Levasseur's "Demography of France," is given:

Pyramid showing the great excess of men 20 to 40 in the city of Paris during the epoch of the public reconstruction of the city under Napoleon III in 1856, and the unusual flatness of the male side of the pyramid just after the close of the wars of the first Napoleon. (Scales, every 1,000, as in preceding figure.)[1]



Thus having illustrated the instinct which prompts men and women to sell their services to the highest cash bidder though they are thereby compelled to put themselves in an artificial or dependent condition—a condition, it is to be remarked, that is socially dangerous only when too many have placed themselves in it—it remains to take up the other instinct which, for the purpose of this chapter, may be separated out from among the passions of the human soul which foster dissatisfaction. This instinct is the desire for visible or objective self-effectuation or renown. The individual experiencing the afflatus of this pleasant but tantalizing emotion naturally feels a sense of repression if compelled by fortune to endure the narrow intellectual horizon of his native village and, especially, the few opportunities it offers for the gratification of his desire to unfold the possibilities with which nature has endowed him, either for doing good to himself or his fellows. His experience both in the world of concentrated directive power at business or political centers and in literature is either nil or is far too meager to counteract his thirst for the power and esteem which he thinks he may obtain in the open compe-

[1] There is a slight error here, as the men's side added to the women's = 1,000.

tition of the distant city world.[1] The failures of his acquaintances, if known remembered, are attributed to incapacity, and the successes of others, he flat himself, have been obtained by the exertion of no greater talents than his o Thus the city is filled with the daring, the restless, and, in the long run, with m who are disappointed, and that phenomena occurs which in ancient Rome now in German cities is called the proletariat.

But the foregoing remarks, it must be admitted, are applicable only to the L and Teutonic races of Europe and America. The Slavs of Russia, at least, an exception. So far from industry inducing a permanent drain of popula from the open country of central Russia to manufacturing centers, the v reverse is the case. All that industry has done is to have made the Rus workman a nomad. During harvest time many factories close their doors, those that keep them open pay wages ranged from 10 to 20 per cent higher t the wages paid in winter. The Russian workman is constantly oscillat between the factory and the farm. He prefers the factory to starvation, tha all. Thus it has become aphoristic to say that the Russian workman has not broken up the bundle of early instilled association of ideas that attaches hin the soil.[2] The country in Russia, as elsewhere, feeds the factory, giving it material, and, as we shall see in a moment, human hands to work that mate up. But when it happens, as in Russia, that the flow of human beings to manufactories is merely a tide that quickly ebbs and flows, no permanency be given to industry which falters in an arrested development. In another p of this report the particulars of the Russian rural association are more fu though lightly, sketched and authorities stated.

In concluding these remarks upon the movement of population two instin have been mentioned separately as exerting more or less influence upon migration of the rural population to the city; it is scarcely necessary to say t these instincts are not to be separated except in thought and in the case of Russian whose necessities drag him to what he deems a prison.

SOURCE OF POPULATION.

But beside the foregoing conception of a man as a being actuated by moti which he follows or refuses to follow there is another conception of him wholly the subject of a force without himself which he is constrained to ob This conception is the outgrowth of statistical inquiry, and owes its introduct to M. Quetelet, who elaborated it in his essay upon man.[3] Any statistical pres tation of the question of the rush to the city is therefore an attempt to expl social facts by relating them to physical causes.

By statistics it is shown that more people are born in the country and surv

---

[1] "I have, certainly, also had always before my eyes the charms of reputation. Over and ab the money view of the question, I wished from the beginning to be something more than a cl in a post-office. To be known as somebody, to be Anthony Trollope, if it be no more, is to much. The feeling is a very general one and, I think, beneficent. But I confess that my object in taking to literature as a profession was that which is common to the barrister w he goes to the bar and to the baker when he sets up his oven. I wished to make an income which I and those belonging to me might live in comfort." (Autobiography of Anth Trollope.)

"Mr. Rogers (one of the founders of the Massachusetts Institute of Technology), working year after year, in a university that was somewhat remote and apart, came to yearn for stimulus of town life and a more scientific atmosphere, and finally, at the age of 49, resigned professorship at the university in order to join his brother Henry in Boston." Pp. 333, 334, and Letters of William Barton Rogers, Edited by his Wife. Boston, 1896.

[2] Leroy Beaulieu's expression.

[3] Sur l'homme et le developpement de ses facultés. Essai de Physique Sociale, par A. Quet Paris, 1835. Hobbes, however, may have been the first to put up man as the subject of phys laws.

longer, are married at an earlier age, and have larger families than happens in the city. Consequently the soil is ever being called upon to support a larger number of persons, while the cities are unable to generate an urban-born population. Statements so broad require that they should be verified; therefore,

1. More people are born in the country than in the city. This is evident to anyone who will trouble himself to read over the following table: [1]

Country.	Births to each couple during their married life in the—		Deaths among each 100 children under 1 year in the—		Number of illegitimate children in each 100 births, under any condition, in the—	
	City.	Country.	City.	Country.	City.	Country.
Franco	3.16	3.28	35.69	28.56	15.13	4.24
Holland	3.91	4.32	36.25	28.90	7.71	2.84
Denmark	3.04	3.34	29.66	22.68	16.05	10.06
Schleswig	3.50	3.69	27.42	23.42	8.38	6.37
Holstein	3.37	3.88	29.92	25.20	15.50	8.74
Saxony	4.60	4.13	39.88	36.22	15.50	14.64
Hanover	2.92	3.65	28.70	26.47	17.42	9.06
Prussia	4	4.44	36.02	29.47	9.80	6.60

The table shows Saxony to be an exception. It is not only an exception to the diminished birth rate in the city, but it is exceptional in every way. The Kingdom is little more than half the size of Massachusetts, has a population of 3,000,000, of which 20 per cent are engaged in agriculture and about 70 per cent, including servants, in trade or industry. Fifty-six per cent of its people live in places of 2,000 or more inhabitants. Another exception is Norway, at least during the years 1860–1870, and though only one-eighth of its population lived in the seven cities (1880) having more than 9,000 inhabitants, the same fact of an increased number of children born out of wedlock in urban communities is shown by the statistics, for in every 1,000 women from 15 to 45 years of age having children [2]—

	Cities.	Country.
Married women from 15 to 45 years who had had children were	311	301
Unmarried women from 15 to 45 years who had had children were	33	20

2. The rural population live longer. The third and fourth columns of the next to the last table show the facts as regards infants under 1 year of age. Considering the whole body of the people of France, it appears that the mortality for the years 1861–1865 was 26.1 in every 1,000 of the city population and 21.5 in every 1,000 of the rural population, and for the years 1878–1882 the average deaths in the 1,000 of city population was 24.3 and in the 1,000 of country population 20.9, or, to state the matter more interestingly, according to the Statistique Generale de France for 1861–1865 every 3,880 country people furnished 100 births to the population, while every 3,570 city persons furnished 100 births (there being fewer

[1] Which is the work of the late Baron von Oettingen, professor in the University of Dorpat. Evidently taken from his Moralstatistik (which has passed through several editions) by M. Levasseur.

[2] Certain restrictions were laid upon marriage by Canton Lucerne, in Switzerland, to wit, parties must not be upon the poor rates, nor likely to come upon them; nor if they are without money or a vocation, and they must be persons of regular habits. Consequently in Canton Lucerne there were fewer marriages and more bastards than in any other Canton of Switzerland, though the sense of responsibility has lowered the number of early marriages. (The Forest Cantons of Switzerland, by J. Sowerby, p. 111.)

children and aged persons in cities). Arranging those facts in tabular form, w have—

	Population.	
	Rural.	Urban.
Births	100	10
Inhabitants for 100 births	3,880	3,5
Deaths among these inhabitants	83	9
Excess of births over deaths	17	

In Sweden it is officially ascertained that the average age at death was, for—

Men.

	1861-1865.	1866-1870.	1871-187
Towns	23.3	24.8	25.
Rural districts	30	33.5	34.

Women.

Towns	28.4	29.9	31.
Rural districts	34.5	37.4	38.

For England and Wales, Dr. Farr has endeavored to show the influence of town life on the death rate of the working classes 35 and over. The table shows that if 2,000 persons over 35 were taken (1,000 living in country and 1,000 in city) that fewer of the 1,000 city people would be alive at the end of fifty years than of the 1,000 country people. For instance, if the supply from below were stopped it would require 3.1 years to remove all the persons over 85 in the country and only 2.4 years to remove all those over 85 in the city. The figures follows:

Died in every 1,000 working [men] between the ages of—	Country.	City.
35 to 45	9	a 1
45 to 55	12	1
55 to 65	25	2
65 to 75	55	6
75 to 85	148	17
Over 85	324	41

a It will be recalled that in the diagram of Berlin's population by age and the figures for Leipzig that 20 is the age of people who flock to cities, bringing with them the vigor of the country. If the city-born population only were counted, the figure would be larger.

Finally, let us take the death-rate statistics of Scotland:

Deaths in every 1,000 people in—	Cities.		Small towns.		Country.	
	Men.	Women.	Men.	Women.	Men.	Women.
1871	30.4	27.9	21.4	20.6	16.7	16.
1880	25.8	22.7	20.7	19.7	16.6	16.
1886	21.9	20.2	18.3	17.9	15.9	14.

3. The people marry earlier in the rural districts. This is sufficiently well indicated by the column of the table on page 1005, showing the greatly increased number of children born to unmarried couples in the cities, despite the ready conveniences of city life. But some allowance must be made for the fact that the

city is a refuge in which the mother can conceal her shame. But overmuch stress should not be placed on this fact, for at Munich, Vienna, and Prague one-half of the births are illegitimate (Von Oettingen[1]); at Paris, Copenhagen, and Brussels one-fourth; at Edinburgh and Milan one-tenth, while at London only one twenty-fifth (3.9 per cent) are born out of wedlock. Besides, as we are not here concerned with the relative sexual morality of city and country, but only with the increase in population, the birth in the city of children of immigrating and unwedded country girls is not favorable to the city birth rate any more than subsequently to its morality. In Sweden it is shown that women cease to bear children (or die) sooner in the city than in the country, to wit:

Age of mothers in the case of 10,000 births (1875).

Age.	Rural.	City.
Under 18	21	25
18 to 20	115	135
21 to 25	1,378	a1,555
26 to 35	4,993	5,338
36 to 45	3,315	2,818
46 to 50	180	86
Over 50	3	3
Total	10,000	10,000

a This does not bear out the contention of the text that marriages are earlier in the country than in the city. The birth rate of Sweden is slightly higher in towns than in the country. The question is, of course, how many mothers were country girls and how many city-born girls.

Compare with the foregoing the more elaborate statistics collected by Mr. Kiaer, director of statistics for Norway, and based upon 133,587 births during the years 1874, 1875, and 1876, furnished by the pastors of congregations of the Lutheran Church, which exclusively predominates.

Number of births in wedlock in each 100 families in Norway.

[The figures express the annual average, based on the years 1874, 1875, and 1876.]

Age of husband.	Age of wife.								Average number of births to 100 husbands between the ages indicated.
	15 to 19.	20 to 24.	25 to 29.	30 to 34.	35 to 39.	40 to 44.	45 to 49.	50 to 54.	
15 to 19									27.0
20 to 24		53.4	48.9						49.5
25 to 29		50.3	45.1	40.1					43.6
30 to 34		52.6	42.4	37.2	32.8	19.1			37.7
35 to 39			41.3	34.6	31.7	19.7	4.6		30.3
40 to 44			30.2	33.1	29.4	19.9	4.9	0.29	22.5
45 to 49				32.0	27.5	17.1	4.6	.36	12.8
50 to 54							3.9	.13	6.3
55 to 59							2.6	.09	2.6
60 to 64								.08	1.36
65 to 69									.66
70 to 74									.38
75 and over									.20
Average number of births to each 100 wives between ages indicated	41.9	51.9	43	36	30	18.1	3.3	.16	19

Compare with the above table,[2] in which it is so conclusively shown the greater

[1] Quoted by Levasseur in "La Population Française," v. 2, p. 400, note.

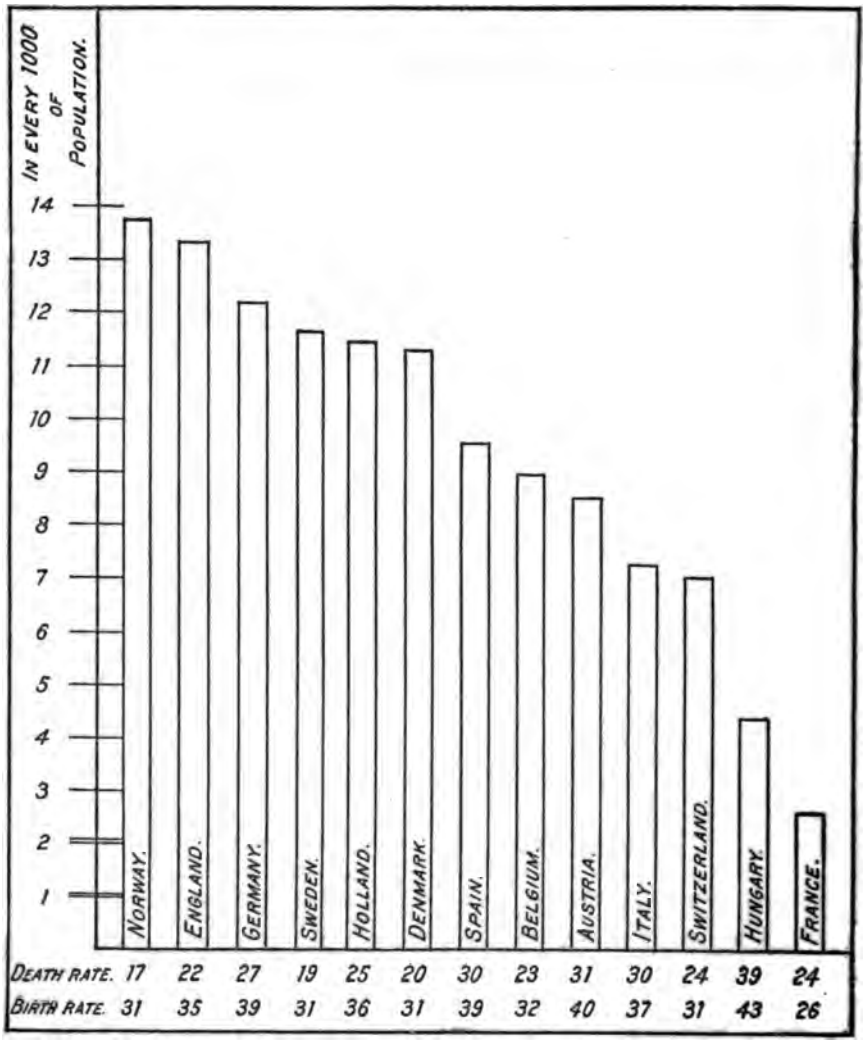
[2] Which it is thought is not difficult to understand. Thus, in every two marriages where the woman is 20 to 24 and the man 20 to 34, there is sure to be 1 child, the chances being 51.9 in the 100 marriages. Where the woman is 25 to 29 and the man 20 to 44, the chances are 9 per cent fewer, namely, 43 in the 100 marriages, and so on.

fecundity of early marriages in the late-maturing climate, and a small city population of the Scandinavian peninsula, with the record of the age of marriage in the Department of the Seine (Paris and its environs).

Age of Marriage.

Department of Seine.	1861-1865.		1885.	
	Men.	Women.	Men.	Women.
City population..	30 years 8 months..	26 years 2 months.	29 years 7 months.	25 years 8 months.
Outside population in department.	29 years 11 months.	25 years 8 months.	29 years 3 months.	24 years 8 months.

Table showing the average annual difference between the death rate and birth rate of western and central Europe during the period 1861–1880, according to the registrar-general of Great Britain and Ireland. (45 Rept., 1884.)

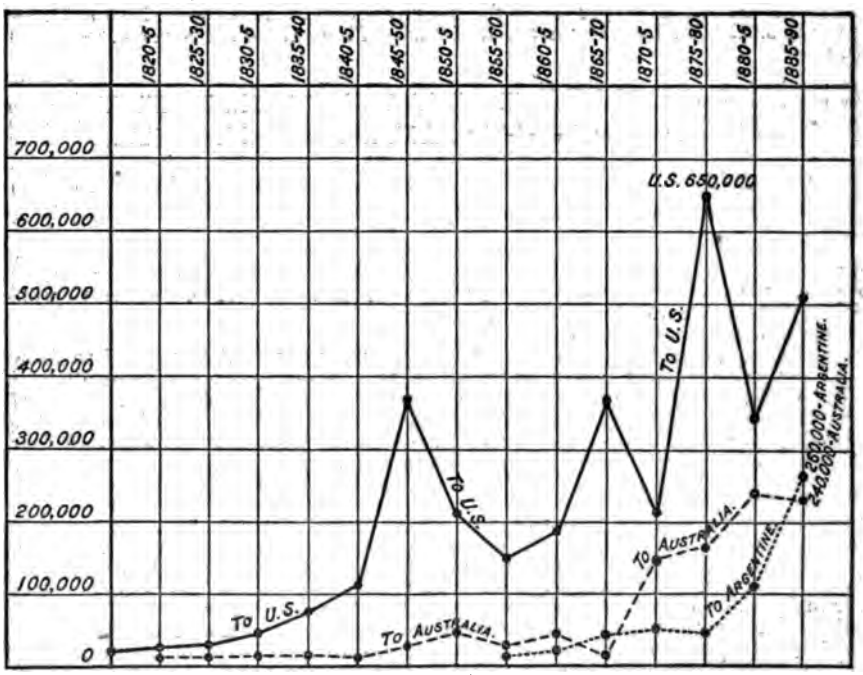


4. The rural family is larger than the city family. If more children are born to a man and wife outside of a city than are born to a similarly connected couple in it, and fewer die in youth in the country than in the city, it certainly follows that the rural family must be larger than the city family. Bearing in mind therefore that increase is made by the rural family, the statistics of the registrar-general for England, shown on opposite page, will show how the countries of Europe have overcome their own death rate, that of the cities, and the loss by emigration.

It only remains to show more particularly how it has been possible for Europe to furnish the United States 15,000,000 of people during the period 1816 to 1888, and 8,000,000 more to other parts of the world, in addition to increasing the size of the city population at home.

Emigration from Europe to America and Australia during 1820–1890.

[The spaces between the lines drawn across the page represent 100,000 emigrants, the zigzag showing the fluctuation from five years to five years.]



Average annual gain of population in Europe from 1830 to 1880 (Mulhall and Levasseur)	9,550,000
Average annual loss to Europe by emigration 1851-1888 (Mulhall)	500,000
Remaining in Europe and crowding to its cities	9,050,000

The diagram will illustrate the course of this emigration, or, as the French and Germans say, the fluctuation in the movement of the population.

From these remarks upon the character of the cooperation in past times of intellectual deadness to produce good government and the necessities of life, and upon the conditions which cooperation at the present day must satisfy as to human aspirations and fecundity, it may appear that the United States is merely a vast colonial enterprise undertaken by European colonists. Such a conception is manifestly unjust, for pari passu with the landing of the promiscuous peoples that disembark on the Atlantic Seaboard a school system has been amplified for the purpose of reducing the collected individuals to a homogeneous mass. Although

all this vast tide has been poured onto the territory north of the Potomac and Ohio and west of the Mississippi, there yet fails to be any indication of a new element having been introduced into the "American" that Webster congratulated his audience on being in 1820. It is very doubtful if there has been as much change in America as there has been in England; certainly not as much as has taken place in Germany or in political circles in France. There is loud complaint of agricultural distress in America, but in the German Empire, by the report of the statistical bureau, nearly 5 per cent of the population, or 771,005 persons, were without employment in the month of December, 1895, as shown by the following table:

In the German Empire there were in June, 1895, 300,000 persons out of employment, and in December, 1895, 771,000. These persons are divided into five classes:

Class.	June.	Per cent.	December.	Per cent.
A. Agriculture (laborers, renters, foresters, fishermen).	38,538 (13,441 women)	0.67	208,797 (106,481 women)	3.61
B. Mining and smelting	167,009 (26,851 women)	2.57	301,471 (45,321 women)	5.96
C. Business	37,310 (5,836 women)	2.50	58,482 (7,851 women)	3.86
D. Domestic service	49,821 (32,466 women)	2.81	103,918 (55,618 women)	5.81
E. Public service	6,674 (2,165 women)		8,337 (2,156 women)	
Total	299,352 (80,749 women)	1.89	771,005 (217,427 women)	4.86

EFFORTS TO RELIEVE AGRICULTURAL DISTRESS BY COOPERATION.

Cooperation in agriculture, as here discussed, is limited to the effort of producers to overcome the difficulties, each as an isolated farmer experiences in disposing profitably of his goods by joining with persons of the same trade. As such it is an effort to insure by force of numbers an adequate remuneration to the whole company against the inequalities produced by inferior mental aptitudes and want of universal opportunities for making lucky hits, which, being so few, create a great noise, arouse spurious hopes, and eventually produce much ruin. It is a very difficult task to bring about the unity of many people in the transaction of business for a considerable length of time, and in the foregoing an attempt has been made to show how troublesome the task is by depicting the efforts of European society to satisfactorily distribute its population into mutually serviceable parts, and how now it has engaged in the work of inculcating, through education, a spirit of unselfish devotion to the welfare of the native land, for the welfare of the nation is, separately from money making, intimately connected with that of the many.

Though at the present day the self-help theories of Schulze-Delitzsch are not secure from sneers, nevertheless the so-called people's banks (Vorschussvereine) of Germany and other countries of Europe are based upon his scheme. He, the so-called father of cooperation, would sweep out of existence the restrictions placed upon trade by the guilds or workingmen's unions which had survived in Germany to his own time (1850), though in England they had been savagely attacked as early as the reforming era of the Tudors, and had collapsed both in England and in France about the era of the American Declaration of Independence.

In 1858 Judge Hermann Schulze stated his programme to be:

At the outset the association will have to be carried on with a certain reticence, because the destruction of the old trade associations is not sufficiently complete, the building ground is not yet so far cleared of the débris of the old system as to enable us to proceed with complete freedom with the work of construction. Besides, we have to fight with the tendency to separatism peculiar to German people, to whom the loss of isolation appears to be a loss of independence, whereas in truth independence is only secured by the hearty cooperation of the once isolated units. Therefore, it seems best to begin with purely economic associations and

trade associations of a very limited character, which assure to members the conditions of a desirable activity of trade without as yet associating them for the carrying on of the trade itself, which will, on the contrary, be carried on by each individual, as formerly, for his own exclusive advantage. Only when the extraordinary power of the principle of association has thus been brought before their eyes and has made them sensible to and ripe for the higher steps in its application, only then should one gradually go on to build up with their help great cooperative undertakings, still guarding against overhasty and inconsiderate attempts, which have generally failed.[1]

As far as Judge Schulze's plan affects agriculture, which was not its original object, an agricultural union not being established on his plan until 1866, it is considered in the last report of this Bureau, at page 1239, to which may be added the dictum of Baron William von Humboldt:[2]

Reason can not desire for man any other condition than that in which not only each individual enjoys the most absolute freedom of developing himself by his own energies in his perfect individuality, but in which even external nature is left unfashioned by any human agency, and only receives the impress given to it by each individual of himself and his own free will, according to the measure of his wants and instincts, and restricted only by the limits of his powers and his duties.

I.—COOPERATIVE IRRIGATION.

The most important effort at agricultural cooperation in America is the collection and distribution of water for the purpose of irrigation. The largest extent of territory artificially irrigated outside of China is the arid region of the United States. Irrigation there has had a checkered career. The early inhabitants of California had appropriated the gold found upon the public lands and in the streams that traversed them, and about 1865 or 1870 speculators in agricultural lands also appropriated the flow of water of convenient water courses. The riparian owners below the place where a creek or river had been turned from its course appealed to the courts, which, in the famous case of Lux *v.* Haggin, decided that the English common law applied to the conditions in California, and that no riparian owner, at the place where the water course passed through or by his property, had the right to divert a whole river into a new channel for the purpose of raising the value of some large tracts of property he was interested in, "dear at 5 cents, to an auction value of from $25 to $100 an acre."[3] The aquatic appropriators, having been shown the impropriety of their action in not consulting individual rights in making "public improvements," soon came to reason, and in 1880 an act known as the Wright irrigation law was passed by the legislature of California. As this act is apparently about to become the basis of whatever efforts are made to redeem the 500,000,000 acres of public lands situated in that region of the Rocky Mountain plateau, where streams are fed in spring and summer by the melting snow banks on the mountain peaks, its provisions and history require attention.

In 1880 State Engineer Hall, of California, stated that he had arrived at several conclusions, and among others—

(1) That the State should not construct irrigation works.

(2) That the State should establish a business basis for enterprise in irrigation projects.

(3) That the cost of works of irrigation should be borne wholly by the lands to be irrigated in each instance.

---

[1] The professional organization of French agriculturists has been completed by the creation of unions or federations of syndicates which are designed to bind together local groups to facilitate their functions and to concentrate their scattered forces, so as to lay before the public authorities a spontaneous and weighty expression of the wishes of the rural population. (Compte de Rocquigny, proceedings First International Cooperative Congress, p. 354.)

[2] Sphere and Duties of Government.

[3] John Bonner, in Overland Monthly, vol. 13, p. 604; Warren Olney, in same, vol. 9, p. 43.

The Wright law was drawn in conformity with these principles, and, as a law based upon the common or State ownership of natural waters and upon the ownership by communities of works for the storage and distribution of water for irrigation purposes, is now in operation in nearly all the arid States.[1]

The Wright law provides for the formation of a quasi body politic and corporate to be known as an irrigation district. This body must be composed of not fewer than fifty (or a majority) of the owners of land susceptible of one mode of irrigation from the same source and by the same system of works. They shall present a petition to the county board of supervisors, setting forth their plans and presenting a bond double the cost of the work they intend to do. If the board grant the petition and accept the bond, it shall divide the district into five divisions of equal size, and in each such division a director shall be elected by the people, or on being petitioned the board may order that three or five directors be elected by the irrigation district in its entirety. The question is then voted upon by those having the right to vote in State elections, and if two-thirds or more of the electors vote for the establishment of the district, it shall be legally constituted. By a majority vote the district may issue bonds, which are payable 5 per cent at the expiration of eleven years and 1 additional per cent each subsequent year until the twentieth. The bonds and interest at 6 per cent are paid by an assessment upon the real property of the district, and all property is pledged for the payment of the bonds.

The operation of the law was impeded. "It is the gloomy misfortune of California," says Mr. John E. Bennett, "that by far the greater part of her land area is owned by persons who, for the most part, do not even reside within the State, and it was expected by the framer of the act that this class would make trouble."[2] The anticipation of trouble was realized in the case of a woman, a nonresident land owner, who in 1894 brought suit against the Fallbrook Irrigation Company in the United States courts on a question as to the right of the State to organize an irrigation district, and the decision was in the plaintiff's favor; that is, she could not be taxed through her land. This decision was overruled by the Supreme Court of the United States in the latter part of 1896, and the Wright law stands.

II.—JOINT INTEREST IN LAND OF FARMERS AND LANDLORDS.

There is another form of what may be called physical necessity of cooperating (the smallness of an element being considered in regard to the largeness of the demand for it) and that is cooperation in cultivating land belonging to a person who may or may not be himself a cooperator in cultivating that land. Thus in China, which is essentially an agricultural community of over 400,000,000 of people, the land is owned by the State, which rents it at a uniform figure, irrespective of the improvement made by the farmer who controls and transmits his holding. In Great Britain there is the landlord-and-tenant class of organization, which in Ireland has produced, it is generally conceded, most lamentable results, for there "the insecurity of the tenant's possession gave him the alternative either of doing nothing to better his farm or of bettering his farm without bettering himself."[3] But the reformation of the Irish system was effected by the application in 1870 of the tenant-right system, which had grown up in the Province of Ulster, to the other three provinces of the island. This tenant right of Ulster gave a fixity of tenure to the farmer and also an interest in the land he cultivated, which interest he could sell to another who wished to take his place. The extension of this local custom to the whole of Ireland was as great an innovation in English legislation as was Hardenberg's interference with the Prussian system of land holding at the

[2] District Irrigation Movement in California.

[3] Robertson, professor Roman law, University of London, in Art. Landlord Ency. Brit. ninth edition. Cf. McCarthy, History of Our Own Times, Vol. II, p. 472, New York edition.

beginning of the century, the prostrated condition of the country to be benefited seemingly leaving no option to the legislator. In this way there is recognized a certain ownership on the part of the tenant as well as on that of the landlord,[1] and the condition of the middle ages is restored, but in favor of the tenant, who is a freeman and is a cooperator with the landlord in possessing the soil and no more an operator—operaius, as the serf was called in mediæval Latin.

In England several attempts have been made by landowners to experiment in the line attempted by the Government of Mr. Gladstone in 1870 and 1880. The earliest and most successful of these is known as the cooperative farms at Assington. In 1830, fourteen years before the commencement of the enterprise of the Rochdale pioneers, the idea suggested itself to a Suffolk squire (Mr. Gurdon, of Assington Hall) that he would attempt to apply, by way of experiment, the principle of cooperation or copartnership to a farm; selecting 60 acres of land of medium quality, furnished with a rough but not unsuitable homestead, he formed his little company of shareholders, all of them taken from the class of farm laborers, to which he gave the name of the Assington Cooperative Agricultural Society. The number of the original shareholders was 15, who put $15 a piece into the concern by way of subscribed capital; the landlord, to give his bantling a chance for life,[2] liberally advanced to the cooperators the sum of $2,000, without interest on loan. The society grew and prospered. The land occupied increased from 60 acres to 130, and the number of shareholders was enlarged from 15 to 21. The present value of the shares is, to use the language of the bailiff (manager), "all of $250." All years have not been equally remunerative, but there has not been any one since the concern started without some little matter to divide. The company have repaid the landlord all the borrowed money, and for all the stock and implements on the farm, which are now their own. The rent of the land is (in 1867) $1,000 a year, the company paying tithes, rates, and taxes. The land is farmed on the four-course system, and ordinarily employs five men and two or three boys. The members (who must be laborers of the parish) are not bound to work upon the farm, but it is understood that if a cooperator is out of work elsewhere he has a claim to employment before any other man. When a cooperator works on the farm, he is paid wages at the usual rate, and if he be inefficient there is no scruple about discharging him. The affairs of the concern are managed by a committee of four, but the practical direction of the farm rests with the bailiff, himself a cooperator as well. Illiteracy is no bar to serving on the committee, yet if a man be not thought sufficiently intelligent he will be refused when his turn comes. The first experiment apparently succeeded so well that in 1854 Mr. Gurdon started a second, which was equally successful as the first until the late strain of bad seasons impaired, if not destroyed, its prosperity.[3]

III.—COOPERATION IN PRODUCTION.

Having thus exhibited two forms of agricultural cooperation to obtain elements which are limited in supply by nature (being land and water) we may turn to the consideration of cooperation in agriculture to provide at remunerative prices those articles which are only limited by the satisfaction of the necessities of human existence.[4]

---

[1] McCarthy, op. cit., Vol. II, p. 478.

[2] It is scarcely necessary to remark that all of this account is given in the pleasant language of the Bishop of Manchester in making his report as assistant commissioner of the agricultural commission of 1867.

[3] The Land and the Laborers, Rev. Charles W. Stubbs, fourth edition, London, 1893, p. 126. Mr. Stubbs tried an experiment on his own land at Granboro Vicarage, Buckinghamshire, England, which proved successful.

[4] There are many cooperative insurance companies in the United States by which farmers reduce the cost of insuring their buildings, but of these there is no occasion here to speak.

"However various the circumstances of the countries of the Continent of Europe," says the report of a recent committee for the improvement of the condition of agriculture in Ireland, "it is a striking fact that we find the same main principles adopted by them all in promoting agriculture, which may be summed up in three words,—organization, representation, education." By organization the committee mean what is here called cooperation and, as they observe, the subject is receiving wide attention. The following is a compilation of reports and statements that the organization of this cooperation has brought out.

(*a*) ECCENTRIC ASSOCIATIONS.

Societies for the purpose of cooperation in agriculture must be separated from those which in the past have owed their structure either to a deep religious feeling, so noticeable in rural communities, or to a disgust with the conventions of middle-class life; for the people who lay the ground plan of such associations are only content when they have isolated their converts from the insufficiently religious world or from the forms current in polite society. Of societies of this description it is not the intention to speak, as we are wholly concerned with persons (possibly mere abstractions) who are willing from pure business motives to voluntarily form a pool or trust for their own benefit by selling in the dearest market and buying in the cheapest. Such an object is in no way connected with religious worship and can not be expected to be cemented by religious belief. It is a mere matter of business interest and must be upheld by the ability of each cooperator to see his own financial good or safety bound up with that of his fellow cooperators, to be contented with nonspeculative profits and mediocrity, and to be willing to work. All these requisites are excessively trying to the nervous system, as was pointed out several centuries ago in a panegyric on the downfall of the little industrial republics of Italy by Machiavelli.[1]

(*b*) THE SYNDICATES OF FRANCE FOR PURCHASING MANURE AND FOR MAKING BUTTER AND CHEESE.

Societies for the aid of agriculture may be divided into three classes—for buying, for selling, and for growing for sale, or for any two or all of these purposes. To these must be added the associations for procuring credit already spoken of in Chapter XXVI of the last report of this Bureau.

The strongest body of agricultural cooperating societies is that of France. They are called by a name well-known in America, syndicates, "Syndicats agricoles," or, in English, agricultural trusts. What is said of these syndicates is merely an abridgment of what is so well compiled by M. le compte de Rocquigny in his "La cooperation de production dans l'agriculture," under which he includes the purchase of fertilizers and machinery, the rearing of animals, and the sale of the productions of the farm.

The 1,500 agricultural trusts of France are founded on the general law of 1884, which allows persons working at the same trade or calling to associate freely for the study and the protection of their economic, industrial, commercial, and professional interests. Some of these societies embrace a whole department (county?), others limit their activity to a township or a parish. The syndicate of agriculturists of Vicune, at Poitiers, and several others have from 8,000 to 10,000 adherents. It is estimated that 200 agricultural syndicates have over 1,000 members each, and that the actual total of syndicated agriculturists is about 600,000. The chief object of agricultural syndicates is the study and protection of economic agricultural interests, which means not only the general welfare of agriculture,

[1] The Prince, cf. Gray's ode to "Vicissitude:"

"Mark proud ambition's march sublime
Up to Power's meridian height,
While pale-eyed envy sees him climb
And sickens at the sight."

but also the special interests common to the members of each association. "The individual efforts of isolated husbandmen, especially if they be small cultivators, are powerless to put down the coalition of adverse interests and to insure themselves a just remuneration for their labor," says M. Rocquigny. It would thus appear that the 600,000 syndicated farmers in France are united for regulating the course of business in that country with no other check than the moderation of their leaders and the opposition of other trade combinations similarly portentous in numbers.

The soil of Europe is far from being a virgin soil. It is said that the Chinese in their garden farming neither impoverish the soil nor buy artificial fertilizers. It is not so in France, and the most serious outlay of syndicate money is for nitrogenous, potassic, or phosphatic fertilizers. The syndicate of Vienne, for instance, buys annually about $200,000 worth, and so on. The influence of the syndicates on the market has been such that "phosphatic manures, for instance, have fallen from 40 to 50 per cent," if produced in France, though the price of imported mineral manures has not been affected. To this reduction of the price of home-manufactured fertilizers must be added the enhanced value of the stuff which was formerly abominably adulterated. Well may M. de Rocquigny say that "the monopoly of those manures was in the hands of traders and agents not always over scrupulous, who took advantage of the ignorance of the peasants to make them pay dearly (say four times the value?) for manures which were wanting in fertilizing power." French manufacturers, it is said, find compensation for honesty and limited profits in a sale increased threefold.

The second great source of expenditure of the agricultural syndicates of France is the purchase of machines to be loaned or hired. These are generally plows (either ordinary or subsoiling), fertilizer distributers, seeding machines, horse hoes, presses, rollers, thrashers, fodder cutters, etc. These instruments are placed in the depots where the fertilizer is stored, and are loaned out at a small charge or even free of charge to the members who desire to use them. This feature is probably one of the great causes of the growth of the syndicates. The thrashing machines are hired out at from 50 cents to $1 a day; in other cases the grain is drawn to the place where the machine is kept and there thrashed, at a cost of 5 cents a 100 pounds, or for 2½ or 5 cents a hectoliter, according as the syndicate or the owner does the work, and so on for the other instruments. The syndicates of the vine-growing districts provide for their "adherents" apparatus for wine making on scientific principles, that would be utterly beyond the purse of small culturists. Sometimes large cultivators combine to procure steam-power-moved machines, and sometimes contracts are made with individual owners of machines to do the work for the members of the syndicates at reduced rates.

There is an effort to secure mutual action among these syndicates. For example, the vineyards destroyed by the phylloxera are best rehabilitated by replanting them with native American grapevines. These were held at such high prices and so much fraud practiced that about one hundred syndicates started nurseries of their own to supply their members either gratuitously or at a smaller price than the vines could be purchased in the market. Thus, the Syndicat Agricole et Viticole de Jujuneux was at first simply a group of ninety-seven vine growers who cultivated for their common benefit a piece of ground planted with American vines, in order to replant their individual vineyards with grafted stock (*Vitis vinefera* on the American stock). In 1893 this association became a professional syndicate, and 150,000 plants grafted by professional persons were distributed in November, 1894. And so on for irrigation, but this last is nothing to be compared to what has been spoken of as done under the Wright law a few pages back.

A very few syndicates, e. g., the Vine Growers' Association, are also used as a means of alleviating distress. For instance, if a member of the syndicate of Thenay falls ill or is hurt, or becomes infirm (empêché par maladie, blessure, ou

infirmité), the active members are, either themselves or by another, obliged to do the necessary work upon his vines, according to the order of the "bureau." Then, again, a very few syndicates are "benevolent societies," as we call them in America. All these syndicates are open to anybody, or, as the French say, "mixed." Proprietors, farmers who rent, farmers on shares (métayers), and laborers all may belong; but the fact is that it is rare to find a laborer belonging to the syndicate. A certain number of syndicates only admit proprietors, and a certain number of syndicates are organized by the laborers to prevent the members of the other syndicates from beating them down to starvation wages and imposing long hours of labor.

Before passing to the subject of cattle raising a word must be said of a very remarkable function, for which a few syndicates have been formed. The Maybug (*Hanneton* or *Melolonta vulgaris*) is a particularly unwelcome visitor in France. The larva of this insect lives upon the roots of plants, and in the spring of the third year comes forth as a beetle. When we find in the canton of Gorron a "syndicat de hannetonnage," we understand that it is no more a producing but a destroying syndicate. One of the 16 syndicates for exterminating hannetons killed 300,000 pounds of the bugs (?)[1] in 1889, and 250,000 pounds in 1892. The destructive and collective inclinations of school children are utilized in this work of prophylactic agriculture. There are also half a dozen syndicates for the destruction of harmful insects, one especially concentrating itself upon "the fly Lyda, which ravages fruit trees," and there are 20 syndicates "for the defense of grape vines against frosts" by means of "artificial clouds," smoke, etc. It is understood that some vine-growing syndicates have made arrangements whereby they can insure themselves against late spring frosts.

There are quite a number of French societies for the rearing of cattle, but that subject will be more fully spoken of under Switzerland's contribution to cooperation where cooperative cattle breeding is at its highest development, as will appear.

The other great object of cooperative production in France is dairying. This is placed, by M. de Rocquigny under the head of "the industrial transformation of products," the transformation of grass into flesh and of scrub stock into good grades being considered a natural rather than an industrial operation. But, however it may be properly classified, it is the world over the most successful form of agricultural cooperation. Listen to M. de Rocquigny's eulogy of that inestimable friend of the farmer, the cow: "In the face of the continuance of the depreciation of the value of every agricultural product cattle have remained the great resource of our cultivators. The bovine race especially, thanks to the merit of our native races, and thanks to our care for them, gives us products that are constantly increasing in value." In his Milk Industries, Professor Lézé, an authority on this subject, remarks that a farm producing 100 quarts (100 liters) of milk should get about 6 pounds (3 kilograms) of butter, representing a value of $1.20 (6 francs), not taking account of the value of the manipulation and transportation to market. On the other hand, if the 100 liters be sold immediately, a return of $1.60 (8 francs) is secured and the labor and transportation saved. Fortunate is it, then, says M. de Rocquigny, that by "collective fabrication" a farmer may raise the value of his milk from $2 to $2.40 for each 100 quarts fabricated. This "collective fabrication" or "cooperation in production" has particular reference to the industrial treatment of milk put in common by the cooperators and assures the best utilization of it possible. The object of this branch of French cooperation is butter and cheese making at a creamery.

The organization of a cooperative dairy is very simple. A group of proprietors having the required number of cattle agree to furnish all the milk from their cows to a proposed establishment, which is built and furnished by the aid of

[1] "The cool nights of spring render this beetle rather torpid and it can be collected in great numbers."—Gustave Henzé, Art. Hanneton.

money either borrowed or subscribed by the associated parties. It is conducted by a manager and a council of administration, who are assisted by a commission of control (executive committee). The receipts from the sale of butter pay for the milk used after taking out a part of the receipts to cover the general expenses and sinking fund. The value of the milk delivered by each cooperator is determined according to the monthly sales of butter, which is a rigorous application of the cooperative principle. In 1888 there were two cooperative dairies in France, and in 1896 there were nearly one hundred.

The great center of butter-making factories is in the region of the Charantes and Poitou, a region much devastated by the phylloxera. The funds necessary to the organization of a factory (purchase of the land, buildings, and machinery) are about $8,000 or $10,000 for an average-sized dairy. Some societies do not have piggeries attached, and some allow their members to make their own butter. The factories sell the butter through the regular channels of middlemen, generally auctioneers. They are not "syndicated" for selling, but only for producing. The butter thus sold in Paris is known as "beurre des Charantes" and amounted to about 6,384,362 pounds in 1893, according to the city statistics. The amounts obtained from the sales are daily turned in to the banks of the Société Générale, which credit the departmental agencies in the neighborhood of the factory. The dairies too distant from such agencies of the Société Générale are addressed weekly by a letter of exchange. The price obtained varies from 32 cents, or even 36 cents, a pound in winter to 18 cents or even less in summer. The average is generally about 25 cents a pound the year round. The packages are about 22 pounds (10 kilograms), plus 200 grams for good weight. The expense of transportation, including the octroi (cost of being allowed to come into the city), and of selling is not quite 4 cents a pound.

It is considered that a cooperative dairy should be able at the lowest to count on about 2,000 quarts (liters) of milk a day. The ordinary general expenses—salaries, coal, oil, packing cloth, etc., and taxes, insurance, transportation, care of material, etc.—are covered by a reserve of from 9 to 15 per cent, derived from the sale of the butter. The director rarely receives more than $200 a year, and must give bond and does not "participate in the benefits." Other employees are an engine driver (mécanicien) and one, two, or three butter makers, who receive from $120 to $240 per year, according to their ability and the value of labor in the locality. These positions, which are very much sought after, are sometimes put in "adjudication," a method not very proper to guarantee ability in those who get the position in that way, so it is said.

The milk is collected at the home of the cooperator by those who contract (entrepreneurs) to do that work. They are called laitiers or tourne-lait, and give bond and receive pay according to the distance. Some of the associations have gone into the business of insuring cows.

Butter making is one form of dairying, cheese making is another. The cheese factory, which the French call by the name of "fruitery," is the oldest form of agricultural cooperation, for it was instituted by the peasants dwelling in the Alps as early as the thirteenth century. At first the cheese maker went around with his outfit to each member of the society, very much as the owner of a reaping or thrashing machine puts himself and his apparatus at the service of a number of farmers for "a valuable consideration." But subsequently this "tacite association," as M. de Rocquigny calls it, was made a de facto society, governed by general laws. The cheese maker was installed in a house, the manufacturing became "sedentary," and was regulated by a council. "In our day," continues M. de Rocquigny, "the organization of the cheese factories has been greatly improved." This apparently has been done by means of instruction, and the following account of a cheese-making school will be of interest:

"Cheese-making schools," says M. Friant, their inspector, in the report upon

agricultural instruction in France, "are establishments rationally organized in which students are admitted to perform all work relative to the utilization of milk in a scientific manner." These schools are managed at the risk and peril of the cheese-making association. The course is limited to one year, and the instruction is free; but each school has two fellowships of $80 [each?]. The State pays the professors, and the association meets the cost of the other necessities of the school. The theoretical instruction comprises elementary instruction and instruction in the chemistry and industry of milk and animal physiology. This theoretical instruction consumes eight hours a week, two for the common-school studies, six for the technical. The practical instruction is the doing daily the work of the cheese factory—making cheese and butter, care of the beehives and piggeries. In addition to this, there is an analysis of milk once a week. There are eight of these schools in France, with two exceptions founded since 1888. The cheese-making factories number 1,983, more or fewer. The sphere of activity of these cheese-making (always taking the word "fruitière" in its dictionary meaning as a mere synonym for "fromagerie") syndicates may be illustrated in the case of the syndicate of the cheese-making factories of the Jura (mountains), of which M. le Marquis de Froissard is president. This is truly a professional association of cheese makers. The object of the association is to protect the common interests of the makers of Gruyère cheese, to see that good cheese makers are selected for the factories, to guard against the jockeying of buyers who wish to get rid of their contracts when the market is falling, to prevent frauds on the part of the cheese makers, to audit accounts, etc.

Other syndicates "of production" are not wanting. There are syndicates for vinification (making wine), for panification (baking bread), grinding cereals, distilling alcohol, making starch, fabricating olive oil, putting up preserves, and making perfumery, the object being to prevent the transformation of raw material into a less raw material by completely manufacturing it at home, thus minimizing at least one of the difficulties that statisticians have in computing the "wealth of a country."

The sale of agricultural products is considered by M. de Rocquigny as the last process of agricultural production, and upon this subject he makes these remarks:

> The agricultural syndicates very generally have proposed to themselves the accomplishment of the sale of their products just as they have brought about cooperation in the purchase of fertilizers, etc. The programme has been to prevent the sale of products below the cost of production and to prevent the artificial depreciation of the market. The means to accomplish this are le groupement des offres and the guaranty of authenticity, by opening new markets, by the suppression of useless middlemen, and by the current of direct transactions thus instituted between the producer and the consumer. But the great difficulties in the way have been recognized. The syndicate is not able to operate commercially, to make and receive binding propositions, to contract for actual delivery (traiter pour des disponsibilités assurées). Its rôle is limited to that of a bureau of information for the buyer and the seller. From this arose the idea of annexing to the syndicates certain institutions organized in such a fashion that they may accomplish what the syndicates can not.

As an agency constituted in this way seems to have the power of subjecting the consumer of agricultural products to the same burdens that the manufacturers of fertilizers in France subject the farmers, and against which combinations the farmers protested, as related on page 1015, no particular mention can be made of it here.

(c) The Object, Organization, and Development of the Cattle-Raising Societies of Berne, Switzerland.

The authority consulted in compiling the following matter is Mr. J. von Wattenwyl-Elfenau, the president of the society whose work is now to be considered.[1]

[1] The Bureau is indebted to Mr. Eugene Germain, United States consul at Zurich, for many documents concerning and illustrations of the cattle raised by this association.

Mr. von Wattenwyl in his report, the first of the kind, to the united Bernese societies, makes these observations:

If we examine the history of agriculture, we find an extraordinarily long-drawn-out development. The son inherited the methods as well as the farm of his father. For generations there was scarcely a change. Thus it was for our time that a change should be made. A general and increasing tendency to intensive culture has spread over Europe. A better acquaintance with the laws of nature and especially the development of competition have completely revolutionized agricultural production. The ease with which grain can be transported caused its cultivation to be neglected in populous Europe and to take colossal development on the broad steppes of America, Russia, and Hungary, which have thus become the granaries of Europe. But the population of Europe continued to increase and industry grow, and as the channels of commerce increased it became necessary for agriculture to produce such crops as would pay a higher interest on capital and labor. From this necessity there arose in Switzerland the business of milk farming (Milchwirtschaft), which is dominated by the idea of the highest possible intensive production of fodder and likewise the highest possible intensive valuation of milk (Sie giptelt in einer möglichst intensiven Erzeúgung von Futter und in einer möglichst intensiven Verwertung der Milch). This is possible to those living near cities, but to others less favorably situated cheese making and condensed-milk manufactories were more remunerative. But there is a fourth means, and that is the rearing of cattle, the really original source of what may be called an intensive milk supply.

Such is the reasoning of the originator of the Bernese societies. There are now at least 184 of these associations in Switzerland. Mr. von Wattenwyl has no scruples about expressing his opinion as to the amount of personal freedom to be accorded to the members of a cooperative society for raising cattle. In organizing such a society the fundamental idea which must permeate the whole body of members is that the will of each individual must be unconditionally subordinated to the will of the organization in those matters where the object of the organization, and consequently its interests, are at stake. Nevertheless the organization must limit its interference with the personal freedom of the members to the most necessary occasions. "It scarcely needs to be pointed out," says Mr. Wattenwyl, "that the formation of a cooperative cattle-raising society will not instantly put a stop to foreign competition in the grain market, nor will it create a flourishing milk industry. The organization as a whole must closely cling to this object: Improvement of the stock gradually but intensively." In short, the contention is this: The Swiss Alps produce the best cattle of Europe. Let them be purchased by foreigners, still the breed of Alpine cattle will degenerate upon the plains of Austria, Germany, and France, and it will be necessary to come to Switzerland, as in the beginning, to procure the blood that is made by the grasses of the elevated valleys and slopes of that precipitous land.

The Berne Cattle-Raising Association, for rearing spotted cattle, is composed of Swiss citizens, who associate themselves for the purpose of protecting and advancing their interests in every particular (nach allen Seiten hin), both at home and abroad, and especially for improving the business of cattle raising. Its authorities are an assembly of representatives and a board of directors, which bodies together elect a president and other directors, who, in addition to the president, are a vice-president, a treasurer, and two members. In addition to these it appears that there is a committee of experts, composed of three members and two assistants, chosen from among the most experienced of the members, who are compelled to act when chosen. This committee selects and buys the bulls and passes upon their register. They also go round inspecting the animals registered to see if they are being properly cared for.

(*d*) GENERAL STATEMENT OF COOPERATION IN GERMANY.[1]

Cooperationists in Germany are divided into two parties; one, organized under th name of "Federal Union of German Industrial and Economic Societies" (Allg meiner Verband deutscher Erwerbs- und Wirthschaftsgenossenschaften), an the other under the name of "Union of Rural Associations of Germany" (Gene alanwaltschafts Verband ländlicher Genossenschaften für Deutschland). Th difference between them is that the first follows the ideas of Schultze-Delitzsch an the other those of Raiffeisen, as explained at pages 1239–1241 of the report prece ing this.

The aims of the cooperators on the Schultze system are these: The furtheranc of cooperation in general, the development of the constitution and the institutio of allied societies, the protection of common interests by united efforts an resources, the formation of mutual business relations between societies. In fac the "union" is a means for the interchange of the experience gained, for counse and help in any case of attack or difficulty which may embarrass individual socie ties, for the powerful union of their strength, for the prosecution and maintenanc of common interests, for defense and unity in the face of threatening situation and dangers, for the formation, finally, of business relations among its members The union defends the interests of associations publicly, by word and in writing to an extent which makes even associations not affiliated to benefit by its action The business of the union is directed by the "Anwalt," who is elected by the asso ciations at their annual congress. The most powerful attack made upon thi organization was made by Ferdinand Lassalle, who demanded the founding o "productive societies" by state help. The union is founded on the idea of self help and a sort of general pooling of the individual interests of the insignificant in a financial sense, members of the community.

The Reichstag—the federal legislature of the German Empire, corresponding t our Federal Congress—has taken upon itself (in 1889) to regulate these societies which were thereafter required every two years to submit their accounts an records to the scrutiny of an independent and expert auditor. At this point w must leave these associations and the political management and oversight of thei affairs and examine briefly into an outgrowth of another organization of them o the Schultze system, called the Federal Union of German Agricultural Societie (Allgemeiner Verband deutscher landwirthschaftlicher Genossenschaften), whic must be kept separate from the Raiffeisen combination of societies, whose name amounts to the same thing. Perhaps it will aid to separate if a table be made o membership, etc., of each.

Liabilities	$11,733,689	$8,164,93
Outstanding loans		$5,016,80

It will be seen that there is quite a difference between the amount of the reserv fund. In the Raiffeisen societies it is not quite $1 to a member; in the Schultz societies it is over $5. The paid-up-share capital indicates a like difference. In

[1] Based on the reports of Dr. Hans Crüger, of the Schultze-Delitzsch system, and of Dr. Cre mer, of the Raiffeisen system, both appearing in report of First International Congress o Cooperation, 1895.

the Raiffeisen societies it is about $2 for each member; in the Schultze societies it is about $10.

Other statistical data (for 1894) concerning the character and operations of the Schultze agricultural societies may now be added.

Raw-produce associations (buying concerns).		Cooperative dairies (selling concerns).	
Number	422	Number	288
Members	22,099	Members	11,196
Cost of goods purchased	$3,778,626	Paid-up share capital	$346,370
Business capital	$150,906	Gallons of milk delivered	32,509,515
Reserve	$79,915	Plant	$1,997,357
		Cost of management	$360,270
		Net profit	$57,102

Milk was supplied to members at a slight reduction from market price.

The societies on the Raiffeisen idea of decentralized self-help seem rather to look to the State (at least, so it is charged by Mr. Cruger, of the rival or Schultze concerns[1]) for financial encouragement where such societies are feeble, or where the State wants them to increase, as in Switzerland and Belgium.[2] But there is another cause, according to the Belgium minister of agriculture, that has promoted the increase of the Raiffeisen banks. The clergy in central Europe, both Lutheran and Catholic, have worked for them, and in 1890 the Catholic Congress pronounced warmly in their favor, and that church gained control in Italy of a system of Raiffeisen banks started by Sig. Wollemborg, or, to use the words of Sig. Enea Cavalieri, of Italy (a Schultzian), "Wrested from the hands of Wollemborg the banner of the rural banks."[3] Sig. Wollemborg had started them. Mr. Mulhall adduces another reason for the progress of these associations or "rural banks:" "Belgians have not been slow to perceive that their money is turned to better account in this matter under their own eyes than by investing it in remote securities."

We are here particularly concerned with a feature of the Raiffeisen system in Germany that is of a more distinctly "cooperative" cast than association for procuring credit—that is to say, cooperation more in line with the meaning of that word as used in this present report. Connected with the central Raiffeisen association or union there is a trading firm which negotiates the common purchase of coal, feeding stuffs, manures, machinery, etc., and which recently has "with very great success," begun to grapple with the difficult problem of common sales of agricultural produce. That trading firm is, like the central bank, a joint stock concern, but with very few shareholders. Independently of the purchases made directly by local associations, this trading firm has in the last two years purchased for and supplied at cheap prices to the union 22,681 tons of artificial manure, 4,707 tons feeding stuffs, 119 tons seeds, 5,430 "trucks" of coal, and about $13,000 worth of machinery; in all, representing about $730,000 worth of goods. Several local centers have put up common warehouses for the storage of agricultural produce and have (independently?) succeeded in negotiating common sales. The mere organization for distributive purposes, existing as a matter of course in the union, has been found to provide facilities for the disposal of produce—potatoes, vine poles, hops, etc.—in localities where such articles happen to be wanted. "The movement is still in its infancy," says Director Cremer.

(e) THE "ALLOTMENT SYSTEM" OF ENGLAND.

While St. Simon, in 1817, was applying the English doctrine of utilitarianism t take the place of Locke's social compact idea, urging, in his book on "Industry, that man is a social being so long as his interests are common with that of others and that industry is the cementing principle of society, Robert Owen was wonder ing how much benefit his 2,000 hands received from the wealth that he and hi partner, Jeremy Bentham, the father of utilitarianism, were making from th machinery used in their factories at New Lanark. To Mr. Owen, the great man ufacturer, is due the idea contained in the dictum that the users of machinery ar growing rich while the workmen are growing poor, and the term socialism, whil the science of sociology apparently is an outcome of the theory of the Count d St. Simon, to say nothing of his connection with positivism and the worship o humanity as developed in the works of M. August Compte. Owen's attempt a forming a cooperative settlement at New Harmony, in Indiana, failed, and so di his movement in England, and after saying that it was necessary to find some lega means of putting farmers on equality with merchants, manufacturers, and other in regard to borrowing money, and that the industrial class (including agricul turists) was the only useful class, the whole St. Simonean movement went down in the overthrow of the second French Republic, in 1848. To both men is due th honor of calling attention to the survival of the fittest in industry, which is now as much debated as Darwinism was in 1860. But instead of evolution we now have sociology.

We have seen that the English Government (that Government so often reproached with laisser faire) began a huge system of the support of the poor about the beginning of the seventeenth century (1601), and it was not slow to take up the cause of the agricultural laborer at the beginning of the nineteenth, when it became necessary to correct the evil of pauperizing the whole lower stratum of the agricultural population on one side and depriving it of commons on the other. The remedy proposed to keep this class of cottagers "buoyant and industrious" was allotments of small pieces of land to the cottages rented by the agricultural laborer. The practical Cobbett, in his Rural Rides, notices the benefit to the laborers of good gardens, especially in the southern counties:[1] "There you see that most interesting of all objects, that which is such an honor to England, and that which distinguishes it from all the rest of the world, namely, those neatly kept and productive little gardens round the laborers' homes, which are seldom unornamented with more or less of flowers. We have only to look at these gardens to know what sort of people English laborers are." In 1819 an act of Parliament empowered the church wardens and overseers of any parish to purchase or take on lease any suitable portion of land and to let such portion of land "to any poor and industrious inhabitant of the parish," to be occupied and cultivated on his own account; and in 1843 a committee of the House of Commons reported very favorably upon the system, and in introducing a bill into the House of Commons Mr. Cowper remarked that "since 1800 no fewer than 2,000 inclosures of commons (public land) had passed and tho' the acreage was not set forth in the returns, it must form no inconsiderable portion of the land of the country. Besides this, the consolidation of small farms so extensively adopted during the war with Napoleon had contributed to deprive the laboring man of his opportunities of holding land. The breaking up of the system of leasing for life also had the same tendency. The result of the combined causes was that, until the allotment system was revived, the English laborer was severed from all connection

[1] Quotations are taken from the fourth edition of Rev. C. W. Stubb's The Land and the Laborers; Facts and Experiments in College Farming and Cooperative Agriculture, London, 1893; History of the Allotment System.

with the land." What Mr. Cowper particularly valued in the idea of the allotment system was the moral effect upon the holder. The management of a garden was an important ingredient in his happiness. But he afterwards added that at least a generation must pass before there would be room for the idea. In 1887 an act was passed called the allotments act. There were in 1890, 455,005 allotments. The main provision of the act is that any six registered parliamentary electors or ratepayers living in the district in the case of towns, or living in any parish of a union in case of the country, may bring the question of the need for allotments before the sanitary authority, which, in rural places, is the board of guardians. If the sanitary authority are of opinion that there is a demand for allotments and that they can not be got on reasonable terms by voluntary arrangements they are directed, by purchase or hire, to get suitable land and to let it in allotments to persons belonging to the laboring population. Public meetings may be held upon the subject. The act does not apply to shopkeepers, assistants, or clerks. In this connection the account of an experiment by Mr. Stubbs, a rector of Buckinghamshire, England, may be of interest:

At the close of the year 1873 [says the vicar] I divided a portion of my glebe land [land under his control as rector], 22 acres, into half-acre allotments, among my parishioners, at an annual rental of 66 shillings [$16.50] an acre. I retained two lots—that is, 1 acre—in my own hands. I have worked it on exactly the same method of husbandry as that of the remaining allotments. That is to say, as it was heavy clay land, not over well drained, but sloping for the most part to the south and west, the kind of crops we grow are wheat, beans, oats, potatoes, mangel-wurzel, carrots, garden vegetables, etc. Now, being interested in collecting what facts I could as to the results to be gained from small as opposed to large culture, I have kept accurate accounts during some years of the outgoings and incomings on my 1-acre farm, and this has been the result: In the last six years of agricultural depression (1878–1884) my net profit on the acre, after allowing fully for rent [$16.50] and taxes, seed, labor, and manure, has been £3 8s. [$16.46]. Let me give in a tabulated form an abstract of my balance sheet from 1878 to 1883:

[£=$4.84; s.=about 25 cents; d.=2 cents.]

Year.	Outgoings.			Incomings.			Net profits.		
	£	s.	d.	£	s.	d.	£	s.	d.
1878	10	0	6	16	6	0	6	5	6
1879	13	18	6	15	1	0	1	2	6
1880	11	18	3	15	6	6	3	8	3
1881	12	7	5	16	1	0	3	13	7
1882	12	3	4	13	15	0	1	11	8
1883	12	13	4	17	4	6	4	11	2
Total	73	1	4	93	14	0	20	13	8

Summary.

	£	s.	d.
Average annual capital employed per acre (outgoings)	12	3	6½
Average annual incomings	15	12	4
Average net profit, or something like 28 per cent on the capital invested	3	8	9½

It may be, perhaps, useful to give the full balance sheet for a fairly typical year. I will take 1881, because in that year one of the leading agriculturists in my neighborhood, Mr. W. Smith, of Woolston, did me the honor to criticise publicly my results, and I can thus give his criticism and my reply.

Here is my balance sheet for 1881:

Outgoings.

	£	s.	d.
Wages of labor	6	7	9
Seed, etc	1	3	8
Manure	1	10	0
Rent and taxes	3	6	0
	12	7	5

Incomings.

	£	s.	d.
Wheat, 5 sacks [20 bushels] from half an acre[1]	5	0	
Potatoes, 55 bushels, at 2s	5	10	
Potatoes, 12 bushels, damaged and sold for pig food		6	
Wurzels, 30 cwt; carrots, 3 cwt	1	15	
Beans, 5 bushels	1	0	
Straw, 1 ton	2	10	
Total incomings	16	1	
Total outgoings	12	7	
Net profit per acre	3	13	

And here is Mr. Smith's criticism (newspaper clipping):

There are a few items very questionable. Take potatoes, said to have been sold at 2 shillings per bushel. Why, I bought fine potatoes last autumn at 1s. 6d., and the market has been clogged ever since. Now, take straw at £2 10s. Why, I bought a lot last autumn delivered home at £2. Now, look to manure; bought £1 10s. for beans and roots, including potatoes. Half his land that must get manured to keep on under such a cropping would need 10 tons of London dung yearly, which, at 6s. 6d. per ton at the railway station, would cost quite 8 shillings per ton on the land, or £4 for the half acre. These three items corrected stand thus:

	£	s.	d.
From 55 bushels of potatoes, at 1s. 6d	1	7	6
From 1 ton of straw		10	0
Extra for manure	2	10	0
Now I must put in interest of money on £12		12	0
Total	4	19	6
Loss	1	5	11
Mr. Stubbs's balance	3	13	7

Mr. Stubbs must show a better balance sheet, or it is of no use for him to come out to show us how to farm. We can not all buy cheap dung, neither can we all sell dear potatoes or dear straw, and tenants' capital ought to bear interest [probably meaning the interest on the "outgoings"].

The following is my reply:

In the first place, let me say at once that of course I am quite prepared to allow that my balance sheet would be valueless as an example of average results if it can be proved that I am farming under exceptionally favorable circumstances of purchase or sale. But this is a contention which, it seems to me, Mr. Smith has signally failed in proving. He asserts, it is true, that I sold my potatoes too dear and bought my dung too cheap. But where is the proof of this? I put down my potatoes at 2s. a bushel. Mr. Smith says I ought to have put them down at 1s. 6d. Why? Because he bought potatoes at that price last autumn. But I was giving the results of my farming, not of his. And I contend that 2s. was a fair "times price" about here for potatoes of my sort last Michaelmas. I know several laborers, at any rate, who sold their potato crop from the same field [the 22 acres he had let out in one-half-acre parcels] at 2s. 6d. a bushel, and more than one got 3s. But for my part I do not argue from that that they were exceptionally lucky in their sale. I only suppose that my tenants were a little better tradesmen than their landlord; they were more successful, in fact, in acting up to that business maxim of selling in as dear a market as you can and buying in as cheap a one, which, I suppose, from his argument, Mr. Smith does not accept.

So again as to straw. Mr. Smith says a ton of my straw is not worth £3 10s., because he can buy straw delivered home at £2.

In reply I would say that not only did I get that value for it, but I knew that my purchaser was giving the same price elsewhere, and that other of my laboring tenants sold their straw at the same price, to be fetched away, to the regular dealer, and therefore, I suppose, to be sold again at a profit. Moreover, one of my tenants who has only just thrashed his corn has been lucky enough to sell it at £3 10s. And then Mr. Smith must know very well that straw off of my allotments is straw, and not straw, couch grass, and thistles.

Then again as to manure. Mr. Smith says I want 10 loads of London dung at £4 to keep my land in good heart. I reply, Why in the world should I buy 10

[1] It may be observed, in connection with Mr. Stubb's results, that Mr. Thorald Rogers, in his England's Industrial and Commercial Supremacy, observes: "Transportation from Chicago to England costing from 36 to 44 shillings for every acre of 32 bushel wheat fairly good wheat-growing land in England ought to produce, the product of every acre in England is protected to that amount" (p. 216; London edition).

loads of London dung at £4 when I can get 10 loads of Granborough dung at half that price with as good results?

By the way, on this question of manure I should much like to ask Mr. Smith, who, I am told, is a practical man, two practical questions.

First. If he considers 10 tons of London dung the fair allowance per acre for farming land once a year, what does he think of the farming operations of his neighbors hereabouts whose land, I venture to assert, seldom gets more than 5 loads to the acre once in even three or four years; and

Second. What is the special agricultural advantage of the large dung heaps by the roadside, which I so continually see left subject to the action of the wind and rain for weeks, with all the best of the ammoniac liquid, assisted by neatly cut channels especially devised for the purpose, draining away for the fertilization of the weed crop of the nearest ditch?

The criticism of practical men [adds Mr. Stubbs] is always valuable, but the following remarks made by two other critics in the year 1883 were not quite so easy to answer as those of Mr. Smith. The first remark was made by the son of a farmer (I am glad to think no parishioner of mine) to the man who is good enough to act as bailiff (manager) of my 1-acre farm: "Why, what a fool you be, John, to let your parson get anything off his land." And the second remark was made to myself by an ingenious member of the capitalist class: "By Jove, Vicar, what a good plan this of yours is to raise the rents of the land!"

Mr. Kebbel, in his Agricultural Laborer (second edition), after saying that the English "yeoman sank into a peasant and the peasant into a pauper under the influence of the inclosure acts of public commons and the growth of large holdings," goes on to say that—

Of the practical utility of the allotment system, apart from its justice in some places and its moral benefit in all, doubts were entertained, but they have now ceased. On the first introduction of the allotment system early in the present century it met with the most violent opposition, not only from the farmers, but also from the clergy and landlords, though it is only fair to say that some of its earliest and most ardent supports were clergymen. The farmers feared that they would no longer get the same amount of work out of their men if these had their own grounds to cultivate. It was also thought probable that they would be tempted to steal seed, straw, and potatoes, and that they would fall behind in rent. None of these apprehensions appear to have been verified, at least to justify dwelling on the argument. While cultivating his potatoes, his turnips, and his wheat, to say nothing of fruits and flowers, the laborer is merged in the husbandman and begins to understand for the first time what is meant by the dignity of industry.[1]

Quite in contrast with the English system is the Russian system, where the serf has not yet become wholly yeoman, peasant, or pauper, but seems to be lingering in a condition that is hostile to industry of all kinds except those hereditary predispositions which prompt him to do the labor necessary to preserve the family clan.

(*f*) The Agricultural Family of Russia.

The fundamental difference between the Russian workman and the workman in the eastern parts of Europe is that in Russia all are more or less countrymen,—tillers of the soil. The workingman who follows a trade is generally a member of a rural community, and his work at his trade is a work carried on to supplement that of the plow, to which he hopes finally to entirely devote himself. Many facts support this assertion, says Mr. von Schultze-Gaevernitz, who has studied this subject and from whose work the matter of this statement is taken. For instance, the sum of the wages paid workingmen is 10 to 20 per cent higher in summer than in winter, notwithstanding which there is a decrease in the number of workers during the summer. In the weaving factories of Moscow and Vladimir, even in case of force (même en cas de presse), only 70 or 80 per cent of the personnel employed in winter are retained through the summer.[2] Indeed, the majority of the factories close their doors during harvest time. Even more than this, the

[1] The Agricultural Laborer, second edition, pp. 106, 107, London, 1893.

[2] Cf. Ianjoul, "La Vie dans les fabriques du gouverenment de Moscou," pp. 86-91, an official report.

Incomings.

	£	s.	d
Wheat, 5 sacks [20 bushels] from half an acre[1]	5	0	
Potatoes, 55 bushels, at 2s	5	10	
Potatoes, 12 bushels, damaged and sold for pig food		6	
Wurzels, 30 cwt; carrots, 3 cwt	1	15	
Beans, 5 bushels	1	0	
Straw, 1 ton	2	10	
Total incomings	16	1	
Total outgoings	12	7	
Net profit per acre	3	13	

And here is Mr. Smith's criticism (newspaper clipping):

There are a few items very questionable. Take potatoes, said to have been sol at 2 shillings per bushel. Why, I bought fine potatoes last autumn at 1s. 6d., an the market has been clogged ever since. Now, take straw at £2 10s. Why, bought a lot last autumn delivered home at £2. Now, look to manure; bough £1 10s. for beans and roots, including potatoes. Half his land that must ge manured to keep on under such a cropping would need 10 tons of London dun yearly, which, at 6s. 6d. per ton at the railway station, would cost quite 8 shilling per ton on the land, or £4 for the half acre. These three items corrected stan thus:

	£	s.	d
From 55 bushels of potatoes, at 1s. 6d	1	7	
From 1 ton of straw		10	
Extra for manure	2	10	
Now I must put in interest of money on £12		12	
Total	4	19	
Loss	1	5	1
Mr. Stubbs's balance	3	13	

Mr. Stubbs must show a better balance sheet, or it is of no use for him to com out to show us how to farm. We can not all buy cheap dung, neither can we al sell dear potatoes or dear straw, and tenants' capital ought to bear interest [prob ably meaning the interest on the "outgoings"].

The following is my reply:

In the first place, let me say at once that of course I am quite prepared to allo that my balance sheet would be valueless as an example of average results if i can be proved that I am farming under exceptionally favorable circumstances o purchase or sale. But this is a contention which, it seems to me, Mr. Smith ha signally failed in proving. He asserts, it is true, that I sold my potatoes too dea and bought my dung too cheap. But where is the proof of this? I put down m potatoes at 2s. a bushel. Mr. Smith says I ought to have put them down at 1s. 6d Why? Because he bought potatoes at that price last autumn. But I was givin the results of my farming, not of his. And I contend that 2s. was a fair "time price" about here for potatoes of my sort last Michaelmas. I know several labor ers, at any rate, who sold their potato crop from the same field [the 22 acres he ha let out in one-half-acre parcels] at 2s. 6d. a bushel, and more than one got 3s. Bu for my part I do not argue from that that they were exceptionally lucky in thei sale. I only suppose that my tenants were a little better tradesmen than thei landlord; they were more successful, in fact, in acting up to that business maxim o selling in as dear a market as you can and buying in as cheap a one, which, I sup pose, from his argument, Mr. Smith does not accept.

So again as to straw. Mr. Smith says a ton of my straw is not worth £2 10s. because he can buy straw delivered home at £2.

In reply I would say that not only did I get that value for it, but I knew tha my purchaser was giving the same price elsewhere, and that other of my laborin tenants sold their straw at the same price, to be fetched away, to the regula dealer, and therefore, I suppose, to be sold again at a profit. Moreover, one o my tenants who has only just thrashed his corn has been lucky enough to sell i at £3 10s. And then Mr. Smith must know very well that straw off of my allot ments is straw, and not straw, couch grass, and thistles.

Then again as to manure. Mr. Smith says I want 10 loads of London dung a £4 to keep my land in good heart. I reply, Why in the world should I buy 1

[1] It may be observed, in connection with Mr. Stubb's results, that Mr. Thorald Rogers, in hi England's Industrial and Commercial Supremacy, observes: "Transportation from Chicago t England costing from 36 to 44 shillings for every acre of 32 bushel wheat fairly good whea growing land in England ought to produce, the product of every acre in England is protected t that amount" (p. 216; London edition).

loads of London dung at £4 when I can get 10 loads of Granborough dung at half that price with as good results?

By the way, on this question of manure I should much like to ask Mr. Smith, who, I am told, is a practical man, two practical questions.

First. If he considers 10 tons of London dung the fair allowance per acre for farming land once a year, what does he think of the farming operations of his neighbors hereabouts whose land, I venture to assert, seldom gets more than 5 loads to the acre once in even three or four years; and

Second. What is the special agricultural advantage of the large dung heaps by the roadside, which I so continually see left subject to the action of the wind and rain for weeks, with all the best of the ammoniac liquid, assisted by neatly cut channels especially devised for the purpose, draining away for the fertilization of the weed crop of the nearest ditch?

The criticism of practical men [adds Mr. Stubbs] is always valuable, but the following remarks made by two other critics in the year 1883 were not quite so easy to answer as those of Mr. Smith. The first remark was made by the son of a farmer (I am glad to think no parishioner of mine) to the man who is good enough to act as bailiff (manager) of my 1-acre farm: "Why, what a fool you be, John, to let your parson get anything off his land." And the second remark was made to myself by an ingenious member of the capitalist class: "By Jove, Vicar, what a good plan this of yours is to raise the rents of the land!"

Mr. Kebbel, in his Agricultural Laborer (second edition), after saying that the English "yeoman sank into a peasant and the peasant into a pauper under the influence of the inclosure acts of public commons and the growth of large holdings," goes on to say that—

Of the practical utility of the allotment system, apart from its justice in some places and its moral benefit in all, doubts were entertained, but they have now ceased. On the first introduction of the allotment system early in the present century it met with the most violent opposition, not only from the farmers, but also from the clergy and landlords, though it is only fair to say that some of its earliest and most ardent supports were clergymen. The farmers feared that they would no longer get the same amount of work out of their men if these had their own grounds to cultivate. It was also thought probable that they would be tempted to steal seed, straw, and potatoes, and that they would fall behind in rent. None of these apprehensions appear to have been verified, at least to justify dwelling on the argument. While cultivating his potatoes, his turnips, and his wheat, to say nothing of fruits and flowers, the laborer is merged in the husbandman and begins to understand for the first time what is meant by the dignity of industry.[1]

Quite in contrast with the English system is the Russian system, where the serf has not yet become wholly yeoman, peasant, or pauper, but seems to be lingering in a condition that is hostile to industry of all kinds except those hereditary predispositions which prompt him to do the labor necessary to preserve the family clan.

(*f*) The Agricultural Family of Russia.

The fundamental difference between the Russian workman and the workman in the eastern parts of Europe is that in Russia all are more or less countrymen,—tillers of the soil. The workingman who follows a trade is generally a member of a rural community, and his work at his trade is a work carried on to supplement that of the plow, to which he hopes finally to entirely devote himself. Many facts support this assertion, says Mr. von Schultze-Gaevernitz, who has studied this subject and from whose work the matter of this statement is taken. For instance, the sum of the wages paid workingmen is 10 to 20 per cent higher in summer than in winter, notwithstanding which there is a decrease in the number of workers during the summer. In the weaving factories of Moscow and Vladimir, even in case of force (même en cas de presse), only 70 or 80 per cent of the personnel employed in winter are retained through the summer.[2] Indeed, the majority of the factories close their doors during harvest time. Even more than this, the

[1] The Agricultural Laborer, second edition, pp. 106, 107, London, 1893.

[2] Cf. Ianjoul, "La Vie dans les fabriques du gouverenment de Moscou," pp. 86-91, an official report.

yield of the harvest directly affects the salary of the factory hands and
persons engaged in industry. If the crops have been large, the peasant posse
enough to satisfy his material needs and pay his taxes has no need to supple
farming by factory work, and the scarcity of hands raises the wages of that
of workmen. If the crops have failed, the plentitude of applications for
diminishes the wage paid.[1] The factory hand looks upon the rural village a
home. When he is forced by his necessities to seek work at the factories, w
he is brought under a régime somewhat resembling that proposed by collecti
socialists or communists, he leads a life of restraint such as a person enroll
the army leads. He has a barrack, poor food, and is watched lest he es
The Russian hates and despises shop work. This feeling is universally prev
among the rural populations.[2] It is the rural association that supports the
and the feeble and brings up the children. The absence of children in the
ment houses attached to the great factories of Moscow and Vladimir is a m
of astonishment to the visitor from other parts of Europe. That sentiment so
acteristic of the English race which is expressed by the word "home" is pr
in the Slavic character in the association of ideas that is engendered by the
liar clanlike organization called by Mr. von Schultze-Gaevernitz "family
ciation" (l'association familiale), and its peculiarity is that it is not based
parentage, but is a true economic association of peasants. Mr. Émile de L
leye speaks for this association. He calls it a family community (la com
auté de famille), and his description of such a community may be of interest

The community of the southern Slav is composed of a large number of build
The principal building is made of wood, is inclosed by a hedge or a palisade
is surrounded by a lawn covered with fruit trees. Here the chief of the fa
(gaspodar) lives with his children, and perhaps another couple with their chil
In the building is the common room where the whole family, 10, 20, 50, or 60,
to eat or pass the evening. In other subordinate structures are chambers for
other members of the family group, and near by the stables, granaries, etc., o
farm. All these make quite an imposing appearance. The more there are i
family the more it is considered that God has blessed the community. Pov
never comes, say these people, to an undivided family. Nevertheless, the
munities never become numerous enough to form a village. There are vill
whose inhabitants have the same name, but they are split up into many hadr
In the case of the people of Croatia I have found three generations united u
the same roof—the grandparents who have retired from work, their children
work, one being the gaspodar, and their grandchildren. The difficulty of fin
employment, the preoccupation to protect the well being of the association
life in common, all are obstacles to too early marriages.[3]

PART III.—METALLURGICAL CONCEPTIONS.

The best distinction that science can make between what is historic and pr
toric in the existence of man is to separate the course of his civilization in
stone and a metalliferous age. The fable of antiquity, born of the hopeful s
which ever prompts man to regret the past and to entertain still more satisfac
conceptions for the future, made the world begin with a happy age of gold, w
passed into an age of iron. But the industrial history of the nineteenth cent
if it has any significance, pronounces emphatically that in more senses than
an age of gold is best approximated through the most varied and unlimited u
iron in its several metallurgic forms. Modern statisticians lack a calculus
will enable them to measure the wealth of England as accurately as the agen
her first Norman king recorded it for his Domesday Book, and no husband
however humble, on visiting the city now removes the glass windows of his d

ing, as economy required the Duke of Northumberland to do during the reign of Henry VIII,[1] nor are the royal pots and frying pans now classed among the Crown jewels of England, as in the reign of Edward III.[2]

But however lavishly nature has excreted iron ore in every geological period for the accomplishment of an iron age, the successful inauguration of such an epoch in human history has been largely dependent upon the deposits of coal laid down during the Carboniferous period. The inestimable value of these deposits has beguiled many persons into speculation as to the limit of the supply; but while the calculations are issuing from the press, discoveries in other lands modify their conclusions.[3]

Though by no means so intrinsically useful as iron or coal is, yet seemingly indispensable to the progress of civilization, the precious metals are from their rarity esteemed as aids of business and ostentation. To gold and silver may be added the many varieties of minerals, stones, and earths that nature has placed at the disposal of man, either gratuitously or through his skill as an engineer.

Skill in engineering, however, is not a gift of nature. It is due entirely to the accumulated efforts made by men of vigorous will, adequate understanding, and patience to overcome the natural obstacles they encounter in the prosecution of their designs. It is the character of such conquests, after a large number of processes have been accumulated, to permit the disentanglement of what is purely local in them and leave a rule of procedure of general application. If the individual instances are generalized to the highest possible degree, the rules are apt to be more valuable to the student than to the practitioner, and to limit the otherwise untrammeled possibilities of scientific generalizations disconnected from practice the idea of the old German polytechnic, with its courses of lectures, has given place to a scheme of instruction composed of lectures, laboratories, and shops combined. When ships of war were propelled by sails it never occurred to the naval authorities to confine the instruction of a midshipman to lectures on the parallelogram of forces. Such a course would have seemed as odd as to measure a man for a suit of clothes by taking his altitude by a quadrant and from that datum to work out his other dimensions by rule and compasses. From the professorial chair, says Prof. Justus Liebig, the pupil receives an abundance of ingenious contemplations, but, bodyless as they are, nothing can be made of them.[4]

The idea of this engineering skill may be illustrated by the operations of the "general staff" of the Prussian army before and during the campaigns of 1866 and 1870. The staff had nothing to do directly with the charging and firing, the enthusing of the men and holding them to their work, its whole object being to place the Prussian army in situations which would enable it to accomplish the exploitation of the army which opposed its march. To do this, the general staff, the chief of which was General von Moltke, had collected, it is said, all manner of details, topographical and other, which molded and modified the application of military science to the exigencies of the campaign. The Napoleonic strategy, on the other hand, is reputed to have been the heavy concentrations unexpectedly made before detached portions of a bewildered enemy, just as in some cases heavy

[1] The Household Book of the Duke of Northumberland, cited by John Henry Parker in his account of domestic architecture in England from Richard II to Henry VIII, Pt. 1, p. 121.

[2] On the authority of Prof. A. H. Hiorns, in Iron and Steel Manufacture, p. 3.

[3] The Carboniferous period is but one of three periods of the Carboniferous age. The Carboniferous age is but one of the three ages of the Paleozoic era, and the Paleozoic era is but one of the four great geological eras, excluding the present. The Carboniferous period, therefore, is but a small fraction, certainly not more than one-twentieth to one-thirtieth of the recorded history of the earth. Yet during this period were accumulated and in its strata were preserved and are now found nine-tenths of all the coal used by man. The name Carboniferous for the period and coal measures for the strata are surely, therefore, appropriate.—Joseph Le Conte, in Compendium of Geology.

[4] Leibig's Autobiography, Popular Science Monthly, March, 1892, p. 658.

concentrations of capital are made upon mineral deposits with great expectations of profit through impetuous engineering.

As an art, engineering is applied to different spheres of human endeavor, but in all the branches of human industry to which the name is given the language used is mathematics, either algebraic or linear representation. The very colorlessness of such a language makes it eminently adapted to record for practical intellects the facts which are supposed to be free from the ideas and passions of the human soul. Beyond this common language there is much that is common to all the forms of engineering, but each of those forms is based upon a different function. Thus it is the function of civil engineering, in its higher forms, to overcome natural impediments to commerce by carrying roadways high over navigable rivers or over or under mountain tops.[1] The function of the mechanical engineer is to utilize the forces of nature by means of machinery, it being the difference between the genius of a Watt and a Newton. But the function of the mining engineer is to relieve nature of the productions of remote geological ages by following her into the crust of the earth.

In speaking, then, of mining engineering as a science, it appears eminently proper to regard geology as its basis. It has been said that mining engineering embraces three specialties—geology, mining, and metallurgy—the divergence between them not being great.[2] Mining connects the duties of the mining engineer with those of the civil engineer and metallurgy with those of the chemist, but neither the civil engineer nor the mere analytical chemist are called upon to have the geological knowledge and experience that should be characteristic of the mining engineer. Geology furnishes him as a practitioner with the scientific ideas respecting his profession, and while he is a student it is the humanities of his course. The cause of the atmospheric changes that produced the ice or the coal-making ages, the footprints in the Connecticut sandstones, and the imprint of a winged and feathered reptile in the lithographic stone of Bavaria, the casting off of the moon mass by the earth and of its rings by Saturn, are well calculated to excite the wonder, inspire the fancy, and challenge the credulity of any but the dullest or the most restricted intellects.

---

[1] The charter of incorporation of the Institution of Civil Engineers, London, defines civil engineering as "The art of directing the great sources of power in nature for the use and convenience of man as the means of production and of traffic in states, both for external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation, and docks, for internal intercouse and exchange, and in the construction of ports, harbors, moles, breakwaters, and light-houses, and in the art of navigation by artificial power for the purposes of commerce, and in the construction and adaptation of machinery, and in the drainage of cities and towns." In France the title of engineer was given to persons engaged in trigonometrical surveying (ingénieurs géographes), etc.

[2] By Professor Ihlseng, of the State College of Pennsylvania, and hear Prof. W. B. Potter, of St. Louis, who, in his presidential address at the 1888 meeting of the American Institute of Mining Engineers, speaks of a "present need in the engineering profession." There is surely no branch of the comprehensive profession of engineering which calls for so much technical instinct and sound judgment as that relating to the broad fields of mining and metallurgy. There are not many mining engineers but have felt how few constants have been determined in their special branches and in what general terms these must be applied. From the examination to determine the nature and extent of mineral deposit and to utilize the properties of the useful substance this supplies there is no step in the many complex operations in which the scarcity of exact knowledge and definite laws does not magnify personal equation and especially call for the exercise of that sound judgment which comes of keen technical instinct backed by large experience well profited by. How lacking in detail, for instance, is our knowledge of the laws and their complex operations relating to the origin and development of mineral veins, and yet how important such detailed knowledge to the practical results we seek to obtain. With the present means, too, how difficult to formulate the strains and stability of materials met with underground or to determine sufficiently to insure complete control of imprisoned water, gas, the effects of heat, and such conditions as affect economy of work and even the life and health of those who labor in the mines. To Professor Ihlseng the Bureau is greatly indebted for the suggestion that it would be opportune for it to begin to compile information in regard to mining engineering. In doing so it is natural that the pedagogical rather than the business side should be here considered.

This conception of geology as the science of the conditions of being—at least of physical being—seems to have been held by English-speaking peoples, for they appear to have striven to make a school of mining a school of science in which the rationale of the phenomena of the earth and its atmosphere are to be taught as a body of doctrine, as the relics of the literatures of Greece and Rome were doctrinized to the everlasting benefit of the people coming out of the Middle Ages, by Erasmus, Melancthon, Sturm, and the Jesuits during the Reformation and counter Reformation of the fifteenth and sixteenth centuries. But geology as the science of the preliminary conditions of being has not yet reached this unity. The subject was first included in compendiums of chemistry[1] and has now to contend with the "science of evolution," which, like the other sciences, except astronomy, is based upon the present residuum of past terrestrial conditions. It is therefore scarcely necessary to add that geology is here considered in its narrow sense as a practical study in the course of the mining engineer, for its indications are the beacon lights that may warn him from unpropitious coasts in the operation called "mining proper," which has been separated by the Lehigh University into three distinct groups and thus described:

The first group is concerned with the application of economic geology to the needs of the engineer, so that he can study and value mining properties, locate appropriately the necessary plant, and calculate the cost of production. It includes the discussion of faults and the means of finding faulted bodies, and practical problems are presented. The subjects of blasting, timbering, and excavating are taught in presence of actual operations. The second course covers the subjects of underground and surface hauling, loading, stocking ores, pumping, ventilation, hygiene, and mining law. The third course treats of the mechanical preparation of ores by the wet, dry, or magnetic methods, and especially of the preparation of anthracite coal.

It will be observed that this conception of "mining proper" stops short at the mechanical preparation of the ores. For coal and rock salt, if either may be called an ore, this is sufficient, but for the metalliferous ores a further treatment is necessary. An outline[2] of the general methods employed in this treatment is presented, mostly in the language of a distinguished writer upon the subject, to complete the definition of "mining engineering" here attempted.

While ores present a great variety of combinations, three general classes may be recognized by the character of the negative element combined with the metal, to wit, native metals, oxides, and sulphides. The metallurgy of the native metals—gold, silver, copper, which are, however, rarely pure—consists usually in a combination of mechanical and chemical processes. When the ore occurs in a vein, as copper and sometimes gold and silver, the vein rock must be crushed and the metal separated by gravity or mercury or other chemicals. In order of simplicity the metallurgy of the oxides follows that of the native metals. The oxide ores contain the most important metals known, such as iron, copper, lead, tin, and zinc. With the exception of iron, all of these are used pure in the arts, and as ores, with the exception of zinc, are heated or fused (deoxidized) by direct contact with ignited fuel, in what the French and Germans call a high furnace (haut fourneau, Hochofen) and the English a blast furnace. The metallurgy of the sulphide ores is more complicated, and, with the exception of mercury and zinc, the processes employed are in general three, namely: Roasting and reaction, by which the sulphur and oxygen are both removed; roasting for the purpose of desulphurization, and then deoxidation, as in the treatment of oxide ores; precipitation, which consists in melting the sulphide ores with some substance having a stronger affinity for sulphur than for the metal to be reduced from the ore. In this last process the unroasted sulphide ore is melted with iron or iron-works cinder and the fluxes

[1] E. g. Brande's Manual of Chemistry, containing the principal facts of the science, arranged in the order in which they are discussed and illustrated in the lectures at the Royal Institution of Great Britain. Mr. Brande in his preface to the third edition (1830) remarks, "the subject of geology has been entirely omitted, as embracing a variety of details not strictly chemical, and as occupying space which I have now consigned to other matter."

[2] By Charles Kirchhoff, M. E., in Johnson's Universal Encyclopedia, 1894.

necessary to fuse the gangue or rock of the ore. Theoretically a blast furnace i the best for this purpose, but in practice a reverberatory or turtled-backed oven with a broad floor upon which the ore is spread, is used, the hot air being rever berated down upon it as the current of air passes along under the dome-shaped roof

It is rarely the case that a metal can be reduced, that is to say, separated fron the ore by one operation. but in this chapter the metallurgical work of the min ing engineer is arbitrarily made to stop at the stage of the process where th metal is no longer an oxide or sulphide, but notwithstanding the impurities i contains is in the state of a block of "native" copper or a nugget of native gol ready for refinement for commercial use.

There is quite another point of view from which the study of the formation o the crust of the earth and its elements are of interest to the most practical. Thi is the refomation or transmutation of mineral substances. Mineralogy, it i said, "is a science which treats of the substances known as minerals—that is, th constituents of the earth as they actually occur in nature."[1] As the mineral sub stances of the earth are generally supposed to be the cooled products of heat and pressure under past geological conditions modern scientific optimism has not failed to engage in the pursuit so dear to the alchemists of the fifteenth and later cen turies, who sought to change dross into gold and carbon into diamonds with that persistence and infatuation which is so powerfully drawn by Honoré de Balzac in his La Recherche de L'Absolu.[2] M. Stanislaus Munier, sixteen years a professor of geology at the French Museum of Natural History, has written a book upon this subject which bears the the title "Les methodes des synthèse en mineralogie." The merits of that work can not be appreciated here. It is sufficient to remark that the difference between a diamond and a piece of coal as worked out in nature's geological laboratory is no greater than the difference between the pig iron from the blast furnace and the decarburized iron from a Bessemer converter; that is to say, between pig iron and steel ingots.[3]

The foregoing conceptions of the work and the possibilities of mining engineering are of a self-regarding or commercial cast. The gist of the matter in an education conducted on such lines is a contract by the school to furnish business with skilled, intellectual operatives, such as no tool or train of mechanism can ever be. Nevertheless, it may not be too premature to speak of the social value of such an operative, not as a purveyor of goods to the market but as an administrator or advisor of those who administer or watch over national resources. A conception of this kind, if understood at all, may, in a country that has some appearance of being a vast enterprise of European colonization and exploitation, unnecessarily seem so absurd that it is pardonable to dwell upon it.

In Pennsylvania the railroad companies own most of the anthracite coal land

---

[1] Bauerman, Systematic Mineralogy.

[2] As was recounted in Helvetius's Brief of the Golden Calf, discovering the rarest miracle in nature, how by the smallest portion of the philosopher's stone a great piece of common lead was totally transmuted into the purest transplendent gold at the Hague, in 1666.

[3] M. Munier thinks that synthesis, in the hands of the practical geologist, may render great services to science, and among others, these especially:

(1) By permitting the formation of types of simple compounds, such as are never realized in nature, but which are valuable for comparing with natural varieties (e. g. Ebelman's crystallization of rubies (spinelles) "who," says M. Chevreul, "by a synthesis, has not only reproduced the crystals of nature formed of silicate of magnesia and the silicate of the protoxyde of iron, but in addition has formed the silicate of magnesia, $SiO_3 3MgO$, which was unknown)."

(2) By completing the series or families of compounds of which the possible members (termes possibles) are not realized in nature (e. g. St. Claire Deville [who first prepared aluminum on a commercial scale] prepared a great number of true apatites taking unnatural bases, so to speak).

(3) By producing perfect crystals rarely found in nature or in amorphous masses for experimental research (e. g. In this way MM. Friedel and Lurasin obtain their material which enabled them to establish the crystalline form and chemical composition of hydrated phosphate of zinc).

(4) By elucidating the circumstances surrounding the formation of different species of minerals and rocks. But this must be done by comparing the artificial ways of producing a mineral (e. g. galena) with that adopted by nature as studied by the geologist on the spot.

and mine the coal, and do so, if not more cheaply, certainly better than individual operators, who endeavor only to get the most and best coal at the cheapest rate, neglecting the smaller and inferior coals, which are never reclaimed, but help to make up the aggregate of the fearful loss per acre of American anthracites.[1] In regard to copper mining, Mr. C. Kerchoff, in speaking of the large increase in the production of copper (1891), observes that it is a matter which is beginning to occasion some comment and is exercising a distinct influence upon the attitude of producers to witness the inroads the present enormous annual production is making upon the reserves of our copper mines. In regard to gold, it is stated[2] that no attempt is made to ascertain the true gold content per ton of the rock crushed, and in consequence the amount that is lost in the tailings or discarded crushed rock is unknown. Though the loss is certainly less than one-third, at which it is sometimes placed, there is still a considerable loss by universal admission.

Mr. Clarence King[3] apologizes for this waste and attributes the neglect of economy and of thoroughness, which distinguish American mining engineering from the best foreign examples, to the "peculiar conditions affecting American mining," which especially require originality and ingenuity, and also "rapidity of execution and the consequent saving of time and interest, for, as a rule, it is true that capital invested in precious-metal mines in this country has always secured quick returns, if any, and investors are impatient of plodding methods."

Mr. King, nevertheless, is free to acknowledge that this Napoleonic strategy has been pushed too far, and better results might have been attained in many instances by more conservative methods.[4] These must originate in the schools.

---

[1] P. W. Shaeffer, C. E., work on American Coal Mining in Supplement to Ency. Brit.

[2] By Mr. C. H. Aaron, metallurgist, in Mining and Engineering Journal, August 10, 1889, being based on facts of his own observation, on private communications, and the official report of the State mineralogist of California.

[3] In Precious Metals, Vol. XIII of Tenth Census. The writer regrets that in making these suggestions he had not before him the corroborating remarks of M. Badoureau (Les Mines, etc., p. 44) to the effect that the exploitation of a mine should not be conducted with the view of obtaining immediate results, but should be done én bon père de famille, for it is important to care for the future. M. Badoureau quotes M. Devillaine (Notice sur la Société Anonyme des Houillères de Montrambert et la Bérandière) to the effect that "a mediocre method, if carried out, presents more advantages than a theoretically excellent method imperfectly executed." Also, M. Hermet (Exploitation des couches puissants, Bul. So. de l'industrie minérale de St. Etienne) to the effect that "It is possible to say that every method of exploitation is good if it is regularly and rigorously applied, and if it satisfies these three conditions: Careful and complete utilization of deposits (bon aménagement et épuisement complet du gite), perfect protection of the miner, and reduction in the cost of mining the deposit."

[4] It is suggestive to compare an account of slow Mexican smelting with the above. "We were fortunate enough to find Señor Mateas's principal furnace in operation. The bellows were working with asthmatic wheezing, a muffled roar of fire proceeded from the massive pile, and the attendants darted here and there on special duty. Low down, at the base of the furnace, several jets of blue flame leaped hissing from the plastered wall, and from their midst flowed a sluggish but continuous stream of the molten metal. With the utmost gravity our host explained his operations; with equal gravity we listened. Out of his hearing, however, we laughed, not at him, but at his mode of smelting down the great old mother mountain, as if her treasure could ever be exhausted in that way. Our return was by the ancient Spanish road, via Tabalopa and the Junta."

Says Darwin, in his journal of his voyage in the *Beagle*, p. 284: "At Yaquil, Chile, when the gold ore is brought to the mill, it is ground into an impalpable powder. The mud [tailings] which passes from the mills is collected into pools, where it subsides, and every now and then is cleared out and thrown into a common heap. A great deal of chemical action then commences, salts of various kinds effervesce on the surface, and the mass becomes hard. After having been left for a year or two and then rewashed it yields gold, and this process may be repeated six or seven times, but the gold each time becomes less in quantity and the intervals required 'to generate the metal,' as the Chileans say, are longer."

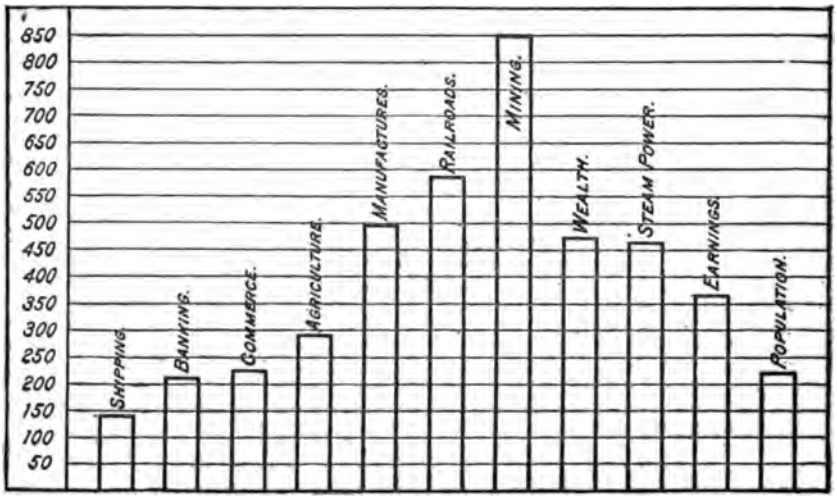
The ores which are treated at Oker, in the Duchy of Brunswick, are lead ores mixed with pyrites, blende, chalcopyrite, barytes, and from 25 to 40 per cent of sulphur. They are divided into five classes, two being treated as lead ores and three as copper. They all contain silver and gold. The working of these ores comprises seven distinct processes, mainly interesting for the separation of the amount of silver—0.01 to 0.02 per cent, and gold, 0.00005 to 0.0001 per cent. (Report of the Director of the Mint, 1886. The Separation of Silver and Gold from Black Copper at Oker, by T. Egleston, Ph.D.)

The function of an educational institution founded upon the scientific or Baconian axiom that man, the minister and interpreter of nature, can only perform his function by observing her, is mental liberality or openness to new conceptions. If schools of science forget their parentage, they will sink into the condition of those academical establishments which have been described by the Scotch philosopher Dugald Stewart as existing in some parts of Europe, which were not (in 1820) without their use to the historian of the human mind, for, immovably moored to the same station by the strength of their cables and the weight of their anchors, they enable him to measure the rapidity of the current by which the rest of the world is borne along.

GROWTH OF THE MINING INTEREST IN THE UNITED STATES AND ITS NATIONAL IMPORTANCE.

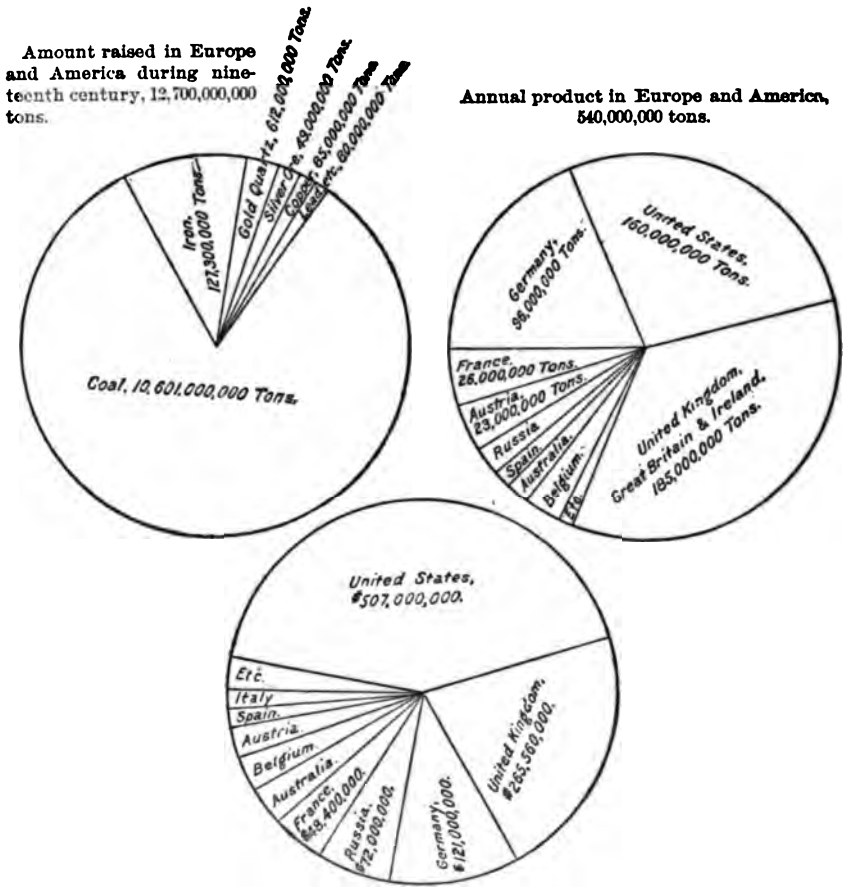
The best gauge of the importance of national interests so far as recognized by the nation is the Federal decennial census. The census of 1790 and of 1800 were capitation enumerations for political use, as required by the Constitution; but the census of 1810 was something more, for it contained a most extensive schedule of questions concerning manufactures, an industry then coming into prominence in New England, where one-third of the population of the country was concentrated on one-sixteenth of the territory east of the Mississippi River. In the census of 1820, under the educative influence of the debates in Congress, the crude questions of the census of 1810 were generalized; but in the census of 1830 the political crisis seems to have caused the inquiries to be confined to the number, color, and personal freedom of the people of the country, which was then more interested in the utterances of Mr. Webster and Mr. Calhoun than in manufactures or the tariff. In 1840 a crude form of inquiry entitled "industry" was inserted in the census and included both manufactures and agricultural products. It was not until the census of 1850—the prototype of our modern census—that mining statistics appear as a part of a new schedule called "social statistics," but not until the census of 1860 were they separated. The growth of the mining interests of the United States since 1860 may be illustrated in a general way by a diagram, slightly rearranged, constructed by Mr. M. Mulhall, the English statistician.

Progress of the United States since 1860, the conditions of that year being taken at 100 per cent.



Both as to quantity mined, value, and capital invested the most important mining industry among European peoples is coal, then iron, and then gold and silver. But in the United States the amount of capital invested in gold and silver mines is equal to the capital employed in both coal and iron mining, though coal employs over three times as many persons as the mines of iron and the precious metals. Compared to these four metals, the other mining industries are relatively of moderate social importance.

The position of the United States in the records of the mining industry of Euro-



Value of annual product, $1,210,000,000.

pean peoples is at the present day almost equal to that of Great Britain in weight of annual output, but far exceeds the mother country in the value of the substances exhumed, as will at once be apparent from an examination of the circles.[1] These circles show the amount of matter raised during the century, the amount raised annually by each nation, and its value. It is evident that Great Britain, the United States, and Germany are the great mineral-producing countries, but that according to value the United States produces almost as much as the rest of the world.

In the Federal Census of 1850 the only industry specifically treated was agricul-

[1] From Mr. Mulhall's Dictionary of Statistics.

ture, then absorbing all interest on account of the speculative movement th coincided with the tide of immigration from Europe, each adult male member which is supposed to have brought with him, on the average, $68.08.[1] In 18 however, coal and iron are considered worthy the dignity of special treatmer Together these two industries have grown in the following manner:

Number of persons employed in—	
1850	16,
1890	334,
For every 100 employed in—	
1850 there were in 1890	1
1860 there were in 1870	2
1870 there were in 1880	1
1880 there were in 1890	1

At the date of 1850 gold mining, and about 1862 silver mining, became a popul craze, effectuating the settlement of the mountainous States west of the Missou settlement in Utah. Movements of this kind are not at all subject to statistic treatment, and the best figures that can be given are that in 1889 56,391 perso were employed in mining the precious metals, at a wage of $2.50 per diem f laborers and $3.12 for miners. The results of these operations were 1,587,000 fi ounces of gold, valued in commerce at about $32,800,000, and 51,354,851 fine ounc of silver, valued in commerce at about $43,000,000, in all 1,813 tons, valued $76,000,000. On the other hand, the base metal iron and the steam-maker co are credited in 1889 with 9,579,779 tons of pig iron and 141,229,513 tons of coa of which perhaps one-third was used for smelting ores containing iron or oth metals and the rest for heating purposes required in commercial and domest life. The value of petroleum was $81,000,000.

The greatness of the production has had the effect of lessening the price of th metals. The flow of the precious metals from America to Europe in the sixteent century had the same effect on their value, and the equilibrium being again di turbed in 1850 by the discovery of the gold fields of California and Australia, th value of gold is said to have been again reduced. The recent discovery of gold i South Africa may have the same effect upon the present value of that metal if th deposits are as permanent in their character and are worked as Napoleonically the other metals. It was computed in the census of 1880 that the shrinkage i the price of coal had been 39 or 40 per cent, of iron ore 25.5 per cent, of ingot co per 24 per cent, while the increase in weight of coal had been 30 per cent fo anthracite, 55 per cent for bituminous, and 62 per cent for iron ore.[2] The functio and the market value of the base metals or minerals is so different from that o the precious metals that the two classes can not be compared properly in the sam graphic scheme, but, in concluding these remarks upon the commercial impo tance of the four great mineral products of the mines of the United States, it ma be of interest to have the increase of the production of the base and the precio class presented separately. (See diagrams pages 1035 and 1036.)

[1] Inquiry of the New York Commissioners of Immigration in 1856.

[2] Mr. Henry M. Chance gives the decline in value of the base metals and the precious meta silver, in this fashion, probably considering the value of the other precious metal to remai stationary for twenty years:

Pounds of metal required to purchase 1 troy ounce of gold.

Silver	a 17.3	a 30.8	4

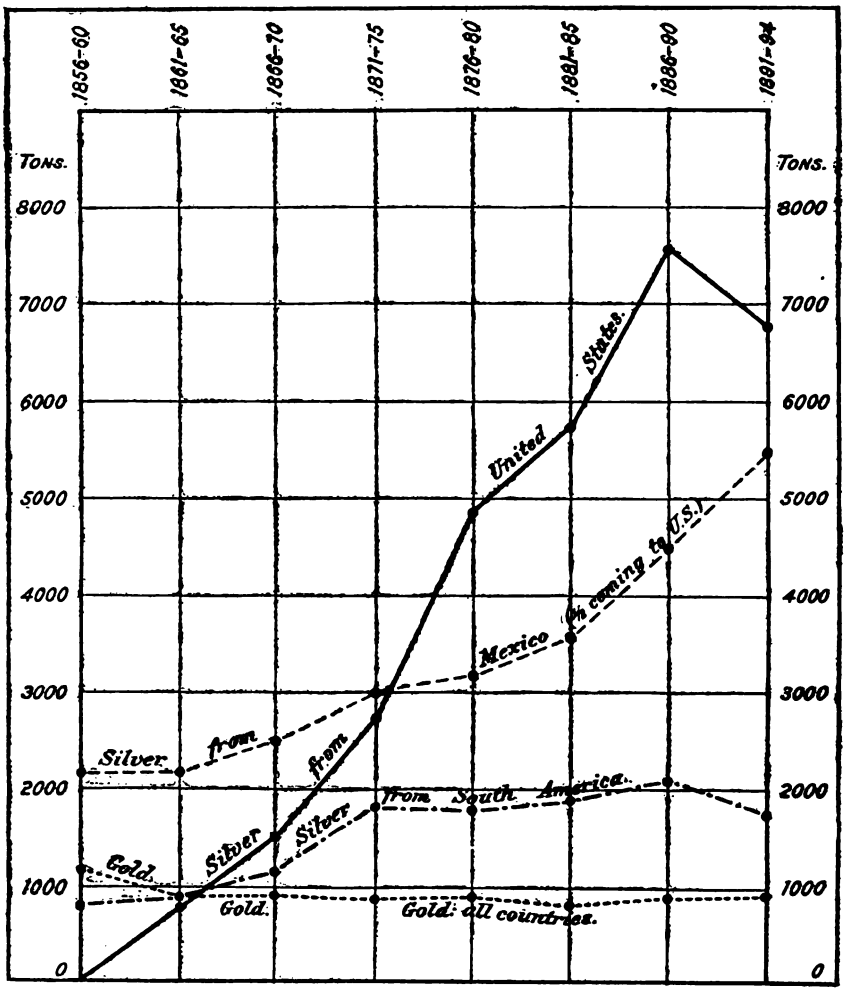
a Ounces.

LEGISLATION RESPECTING (1) MINING CLAIMS, (2) MINING INDUSTRY, (3) SAFETY OF THE MINES.

1. MINING CLAIMS.

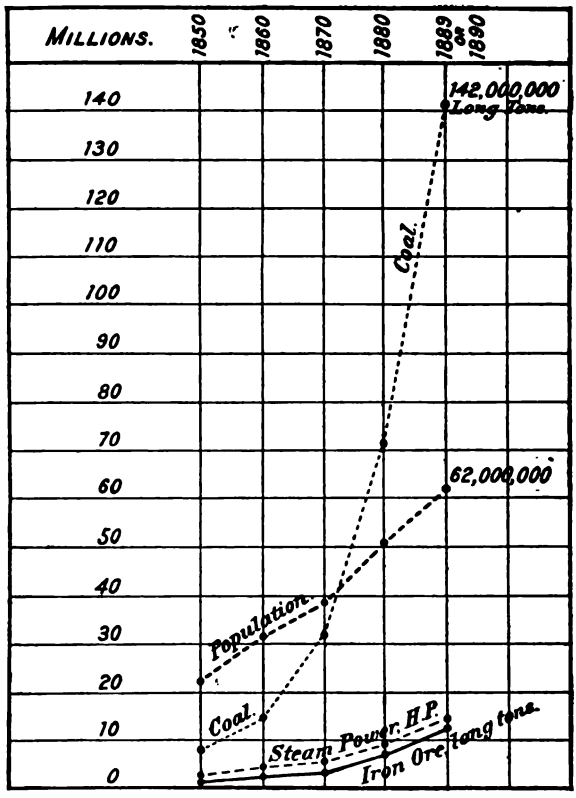
The mineral lands of the United States west of the Allegheny Mountains and the headwaters of the Ohio were originally the property of the people. In the ordinance of 1787 "for the disposal of lands in the Western territory" it was provided

PRECIOUS METALS.—*Production of the precious metals by the mines of the world since 1856.*



that "one-third part of all gold, silver, lead, and copper mines to be sold or otherwise disposed of as Congress shall hereafter direct" were to be reserved for the benefit of the public Treasury. Congress did not legislate upon the matter until

BASE MINERALS.—*Production of coal in the United States since 1850, compare with population, iron ore, and steam power, the production of the two last bein almost entirely a function of coal.*



1807, and then only in an incidental way. In an act of that year called "An act to prevent settlements being made on lands ceded to the United States until authorized by law," there is a proviso[1] to the effect that in all cases where "the tract of land includes either a lead mine or salt spring no permission to work them shall be granted without the approbation of the President of the United States, who is hereby authorized to cause such mines or springs to be leased for a term not exceeding three years and on such conditions as he thinks proper." By another act of the same year authorizing the disposal of the public lands west of the Ohio, it is enacted[2] that "the several lead mines in the Indiana Territory, together with as many sections contiguous to each as shall be deemed necessary by the President of the United States, shall be reserved for the future disposal of the United States, and any grant which hereafter may be made for a tract of land containing a lead mine which had been discovered previous to the purchase of such tract from the United States shall be considered null and void, but the President is authorized to lease any lead mine which has been or may hereafter be discovered in the Indiana Territory for a term not exceeding five years."

For forty years this policy was continued under the Secretary of War, who was practically the minister of frontier affairs in those days. During that period

[1] Revised Statutes, vol. 2, p. 446 (Boston, 1845). [2] Revised Statutes, vol. 2, p. 449.

the value of the deposits of copper in the upper peninsula of Michigan became known and the same policy of leasing was applied to them. But the period was not in concord with such a policy. In 1846 the first magnetic telegraph line in the world, the property of the Government, was ordered to be sold or leased to anyone who was willing to work it for what he could get out of it, and by another act of that year one-third of the national district was retroceded to Virginia on the ground that Congress should have under its exclusive control no more territory than was absolutely necessary. During the same year, 1846, an act was passed which authorized the President of the United States "to sell the reserved mineral lands in the States of Illinois and Arkansas and Territories of Wisconsin and Iowa, supposed to contain lead ore,"[1] and among the acts of the following year another act was passed providing "for the sale of mineral lands in the State of Michigan." But the system upon which the mineral deposits of the public lands of the people of the United States were to be worked was yet to be established.

By accident in 1848 the superintendent of Sutter's Mill was made aware that gold was to be found in the soil of California. Such news travels fast despite all efforts to secrete it, and as other States have come into the Union as aggregations of agricultural and village communities, California came into being as an aggregation of mining camps and the business dependent thereon. Men who have braved shipwreck and starvation in rounding the "Horn," or massacre or torture in crossing the "Plains," are not wont to wait long for Congressional action in matters where their business interests are concerned, and with an Anglo-Saxon instinct proceed to organization immediately, recognizing that individual liberty is due to a social compact and sanction.[2] Among the many thousands of manifestoes of local organizations in California is one issued at the meeting of the miners of Dry Creek, Rancherea Creek, Amador Creek, and Sutter Creek, in June, 1851, "in accordance with a previous notice." At this meeting it was resolved[3]—

First. That rules and regulations for the security of the peace and harmony of the miners who are now or who may hereafter be engaged in prospecting and working quartz mines are positively necessary.

Second. That in compliance with that necessity, we do hereby ordain and establish the following rules and regulations for the government of the district within the following bounds, to wit: All that portion of the county of Calaveras that lies south of the dividing ridge between the Consumes River and Dry Creek, and north of the Mokelumne River.

Third. That the size of a claim in quartz veins shall be 240 feet in length of the vein, without regard to the width, to the discoverer or company, and 120 feet in addition thereto for each member of the company that shall now or may hereafter be organized.

Fourth. That no claims hereafter made shall be considered good and valid unless the same shall have been staked off in conformity with resolution third and written notice of the size of the claim and number of men in the company posted upon a tree or stake at each end of the claim, together with the date of day when the claim was made, and all claims that are now made shall be staked off in conformity with these resolutions within five days from the date of the adoption of these resolutions.

Fifth. That the size of the claim, the number of men composing the company that holds the claim, together with a brief description of the location of the same so that it may be identified, shall within ten days after the claim is made be filed in the office of the justice of the peace in whose district the same may be located. And all persons holding such claims shall file the same within ten days from this meeting.

[1] President Polk had pointed out in 1845 that the leases had only given in four years $6,355, while the Government persons required to "superintend the lessees" cost $26,111. He recommended that the lands be sold, but that Government should reserve "an equitable percentage of the gross amount of mineral product." It may be added that in the Lake Superior region a large proportion of the mines are leased by the present owners, and no difficulty results, and Michigan is now the largest iron-ore State in the Union.

[2] In 1847 California had a population of 15,000; in 1850 it had increased to 100,000.

[3] Tenth Census, Vol. XIV: Mining Laws, p. 271.

Sixth. In all cases where claims are held by a company working jointly they shall not be required to work in more than one place, but when held by individuals each several claim must be worked.

Seventh. Whenever a claim has been abandoned and such can be clearly proved before the justice of the peace where such file was made, said claim shall be forfeited to the person or persons establishing such proofs.

Eighth. That these rules and regulations and proceedings be signed by the president and secretary of this meeting and filed in the justice's office at Drytown.

Thus was organized the Drytown mining district,[1] in the same manner, and the necessary changes being made, for the same purpose as that for which the early colonists of the Atlantic Coast organized themselves into a "town" for the purpose of civil government, or into a parish for the purposes of religious worship, or into a "school district" for the purpose of educating their children.

But the founders of the many mining districts established on the plan of the Drytown mining district were freebooters. The land they appropriated was the property of the people of the United States. This was no secret. The preamble of the resolutions creating the Springfield mining district was expressed in these apologetic terms: "California is and shall be governed by American principles. * * * And as Congress has made no rules and regulations for the government of the mining districts of the same, and as the State legislature of California has provided by statute and accorded to the miners of the United States the right of making all laws, rules, and regulations that do not conflict with the constitution of California, in all actions respecting mining claims we do ordain and establish," etc. In 1850-51, General Frémont, then a Senator in the Congress, introduced a bill to lay a ground rent upon the miners. A violent debate ensued, in which many proposed to sell the lands in large blocks; but through the efforts of William H. Seward and Thomas H. Benton the matter was allowed to drop.[2]

In 1865 the Federal Government finally acknowledged what was called a "possessory" title of exploitation, but still retained its ownership or "paramount" title, at least as far as the State of Nevada was concerned, which was the second State admitted having a preponderatingly large mining population. It was the law of 1866, however, that made the mineral lands of the United States "free and open" to the "citizens of the United States and those who declared their intention to become such," at a cost of $5 an acre and the expense of survey and registration of the claim in the land office of the United States.[3]

The legislation of the Government of the United States is not the first effort of a European civilization to regulate the disposal of mineral wealth beneath the surface of land owned by the people or individuals. It is, therefore, befitting that the main provisions of the American land laws, as far as they govern the disposal of mineral lands, should be preceded by a retrospective glance at the early principles that inspired the codes of Europe, not including whatever laws may

[1] In later mineral States this form may have sometimes degenerated into a farce, as was possible in a frontier community having some persons more experienced in the forms of procedure than in the matter of honesty. When gold was discovered in 1848 the news brought an unparalleled immigration into the mining counties of California. "Mining for the precious metals was a new industry to the people of the United States," says an official report on the Precious Metals in the United States. They had no laws applicable to the wants and necessities of miners. The title to the lands was in the United States and it neglected for eighteen years to pass any law with regard to mining. The miners themselves made rules and regulations for their own government. Under these customs and usages $1,200,000,000 worth of gold (1886) have been extracted from the mines of California, $900,000,000 of which came from the ancient river channels in Nevada County alone, and more remains than has heretofore been taken out."—Gold and Silver Mining in California, in Report of Director of Mint for 1886.

[2] On this point of the nonaction of the Federal Congress, the work by Mr. C. H. Shinn, entitled "Land Laws of Mining Districts," 1884, has been used. Mr. Shinn makes much of the resemblance, as was the fashion during the eighties, of the mining district to the "folk moot" of the Anglo-Saxons, and even of the system of the squatters of the early Teutonic and Aryan race. It is the adherence to the idea not the instinct that is Anglo-Saxon.

[3] Statutes at Large, 1865, Chapter LXIV (p. 441), and 1866, Chapter LXXIII (p. 43).

have governed the quest of precious minerals on the part of Spanish adventurers and the English and French buccaneers who relieved them of the products of their exertions as it was being carried across the ocean to Spain.

It might be assumed that as a bird of the air is the property of whomsoever has the cunning or skill to kill or entrap it, so the discoverer of mineral deposit might be regarded as at least partially entitled to the subterranean wealth his ability or fortune has led him to find, for in the civil law of Rome the discoverer of hidden wealth was entitled to share equally with the owner of the soil beneath which had been found the treasure—the res nullius, the thesaurus inventus, the treasure trove of the Roman and English lawyers. The depositor of the discovered treasure might well be considered as having practically abandoned it, for he had left no statement of his whereabouts nor of his intentions, and with the same propriety it might be held that Nature, in depositing mineral wealth by aquatic or thermic action, had relinquished all right in her work to the happy individual that Providence should send to find it. Two conditions have interfered with these suppositions, one of which has been called by the father of political economy "the sacred thirst for gold," and the other is the "right of eminent domain," a product of the feudal ages, when there was no land without its lord and the surface of the earth was owned not by those who tilled it, but was held in fee as a reward for military or theological services past, present, and to come. In ancient Greece, Macedonia, and Spain the State left mines of copper and iron to individual proprietors, though grasping those of silver and gold.[1] The right to the mines being therefore in the mediæval monarch or lord paramount—by "jus commune, quasi gentium," as Grotius names it—the right of the monarch was easily merged into the right of the people when the monarch became the first servant of the State, to use the expression of Frederick the Great of Prussia.

The English law of mines is simple: The owner of the surface or agricultural soil owns the mines.[2] The final overthrow of absolute monarchy in England in 1688 was accomplished by the land-owning gentry, and in the first Parliament of William and Mary a law was passed relinquishing all right of the State to ownership in lead, tin, or copper mines.[3] Quite in contrast with the English method is that adopted by the French. The revolution in 1789 which overthrew the old monarchy was, it is now claimed, a victory of the business men, lawyers, doctors, and merchants,—the bourgeoisie. In 1791 the first law regarding mining claims passed by a legislature appointed by the people dealt with mining claims in some degree as the Roman lawyers had dealt with treasure trove.[4] This law, due to the influence of the celebrated Mirabeau, declared that the State could arrange for the exploitation of a mine without the consent of the proprietor of the surface, though reimbursing him to double the amount of any loss occasioned to him by such exploitation. But the law of 1810 first clearly settled the particulars of such arrangement. The provisions of this law are as follows:

The Government has the monopoly of granting permission to mine. It shall select from the applicants for such permission such person or persons as may appear most likely to do the work without waste or failure. It may pass over both the discoverer or the proprietor of the surface, but the discoverer has a claim (the amount to be fixed by the State) against the person to whom the right to mine is given. The proprietor of the surface is also considered. He is forbidden to mine on his own property unless authorized to do so by the State, just as in a city a building permit is required, but if he be not the party to whom the grant to mine is given, that party is required to pay him such a sum under such conditions and in such a manner as the Government shall decide when granting the right to mine. Thus the right to mine, though "real property," is entirely dis-

[1] Merivale, The Romans under the Empire, Chapter XXXII.
[2] But the Government claims all workings below low-water mark.
[3] Blackstone, Book 1, Chapter VIII: The King's Revenue.
[4] Justinian, Institutes, II, 1, 39.

tinct from the ownership of the soil, yet as real estate is subject to all the laws which govern that species of property, except that it can not be divided.[1] The State supervises the working of the mine, with the object of preventing waste of the matters contained in the vein, to prevent damage to the surface soil, and injury (explosions?) to mine. For its trouble the State requires a fee of 2 cents for each hectare (2.4 acres) and a proportional part of the net product up to a fixed amount, and then 5 per cent for all over.

In the United States there have been three sources of legislation—the law of the mining district squatters as they took possession of the lands for mining purposes, the laws of the State, and finally the acts of Congress of 1866 and 1872. Mr. Shinn thinks that the laws of the mining district if collected would fill 2,000 pages. But what is essential in them is here supposed to have found its way into the Federal and State laws, which are epitomes of them. The Federal act of 1866 is based by implication upon "the local customs or rules of miners in the several mining districts," and is partially a ratification of those customs, partly a generalization of them for the purpose of preventing contests and fraud, the fee of $5 an acre mentioned in the act being, perhaps, merely sufficient to cover the costs of surveying, recording, etc. It is to be remarked that there are several United States inspectors of mines in the Territories not yet formed into States.

2. THE TARIFF ON IMPORTED MINERALS.

There are two features of public laws which are more or less intimately connected with the industry of mining which may be spoken of in this connection on account of their dignity, which lifts them far above provisions for regulating the business of private companies or persons, or for deciding actions at law. These are (1) the tariff laws passed by Congress since the formation of the Republic in 1789, and (2) the laws which have been passed to protect the life and limbs of the miner by the State legislatures.

Principal minerals mentioned either as ore or unwrought material in the more important tariff laws of the United States since 1789.

[From Tariff Acts of the United States. Government Printing Office, 1896.]

Year of law.	Coal, duty on, as—			Iron, duty on, as—

a Plates and sheets 30 per cent ad valorem.
b Ad valorem.
c $0.035 for sheathing copper.
d By pounds, pure copper contained in ore. Mr. Taussig claims that copper ore paid 5 per cent ad valorem before 1869.
e Ore and matte free.

3. Protection of Miners.

If there be exclu led from consideration the stricken field of battle, it will be found that the most deadly occupation that man can engage in is mining, especially coal mining, an occupation in which by far the largest number of miners are engaged. In 1886 there were 916 miners killed by accident in England, 180 more male persons than the railroads succeeded in killing of their passengers and employees. For every 57,000 tons of mineral raised in Great Britain during the period of 1851-1860 one miner was killed outright. Of the maimed no figures can be given for England; but in Belgium from 1880 to 1889 the annual average was 210 killed, and 74 so severely hurt as to be incapacitated for work during six months or more. In England there has been a loss of 33,000 lives from 1851 to 1888, the victims being killed upon the spot. In 1895, 1,198 lives were lost. Yet it appears that this is preventable, for from 1851 to 1860, one miner in every 245 was killed; in 1861 to 1870, one in every 300; in 1871 to 1880, one in every 425; in 1888, one only in every 484. At the last European congress of miners Mr. Möller introduced a resolution which he contended would prevent this destruction of life. There should be a state inspector, he thought, who should visit the mine every three months in the case of ordinary mines, but once a month in the case of dangerous mines. There should also be an employee appointed by the mine owners to supervise dangerous mines under the control of the State, and finally there should be workingmen inspectors selected by their comrades and paid by the state, who should have a permanent control of the carrying out of the work set in motion by the state inspector. It is noticeable that both in Germany and England great respect is paid to the scientific knowledge of the inspectors by the miners, but that they put very little faith in their practical knowledge of the working of the mine.[1]

[1] Cf. Mining Inspection a Sham, Nineteenth Century, June, 1885.

The great causes of death in mining are two: Fire-damp explosions, mostly co fined to coal mines, that "blow" out methane or marsh gas, and roof-falls ar caving in of the sides of the galleries.

The cause of an explosion in a fiery mine has received, as may be readi imagined, considerable attention. In the early part of the century Sir H. Dav experimented upon the inflammability of the gas that causes the trouble, whic he said, when mixed with from four to twelve times its volume of common a may be exploded by introducing a light, resulting in suffocating the miners or i shooting them out of the mine as though they had been projected into space by a enormous cannon. Another English chemist, Mr. Faraday, on the other hand, i a report upon the explosion in the Haswell colliery, remarked many years ag "That there is every reason to believe that much coal gas had been made on thi occasion from the coal dust in the very air itself by the flame of the fire dam * * * and that much of the carbon in this dust remained unburnt only fo want of oxygen." In an address on the Chemistry of Colliery Explosions Due t Gases Derived From Coal Dust, Mr. Donald M. D. Stuart remarks that the explo sions at the nongaseous "Camerton," and "Tunesbury" collieries were originate by the heat generated by the blasting powder which, being 3,200° to 3,600° F., woul so operate upon and dissociate the coal dust suspended in the atmosphere that i would be converted into ordinary illuminating gas, or a "gas" composed of 51.2 per cent free hydrogen, 38.84 per cent gaseous hydrocarbons, and 10 per cent othe bodies. As soon as the free hydrogen of this gaseous mixture meets a considerabl quantity of common air (which contains free oxygen) the hydrogen and oxyge unite, producing a flame and an explosion. This explosion liberates more hea and sets up another train of chemical changes which culminate in another explo sion when the moving current reaches another place having a sufficient supply o oxygen to ignite it.[1] Again, it appears that finely divided coal left behind in th "sides" of the working places is especially liable to ignite from so-called sponta neous combustion due to the rapid oxidation that is set up when the slack of coa is brought in contact with air.[2] The efforts to obtain safer explosives and illumi nating apparatus for mines will be spoken of hereafter.[3]

The second great cause of the mortality and bodily dismemberment of th mining population is the neglect of the engineer, either from economy or venture someness, to shore up the excavations he is carrying out.[4] As timber is not scarc in America, this evil is less likely to happen here than in Europe. But there is danger in the use of wooden props in the warm, moist atmosphere of the mine readily recognized by those who have lived in the moist climate of Florida o other subtropic clime. This danger is the dry rot of timber, and is peculiar to ill ventilated places. The quantity of water daily flowing from the Sutro tunne was, in 1879, 12,000 tons, and its temperature at the mouth of the tunnel wa

[1] Nature, April 22, 1897. Methods of overcoming the dangers resulting from the accumulatio of coal dust in mines. M. Schmerber has studied in the Genie Civil the different means recog nized as overcoming the dangers of coal dust in mines, and notably those having the object t dampen the dust. The last named method in its several varieties has been more and mor adopted, and may be classed in five different categories.

1. The use of salt or other body which has a great affinity for water.
2. Use of water vapor.
3. Setting up of damp surfaces.
4. Watering by means of reservoirs which are either fixed or movable.
5. Watering by canals and subterranean conduits.

It appears that up to the present the method of moistening the coal dust is the most effectiv in overcoming the dangers of having the atmosphere of coal mines saturated with coal dust.- Revue Scientifique, November 20, 1897, p. 665.

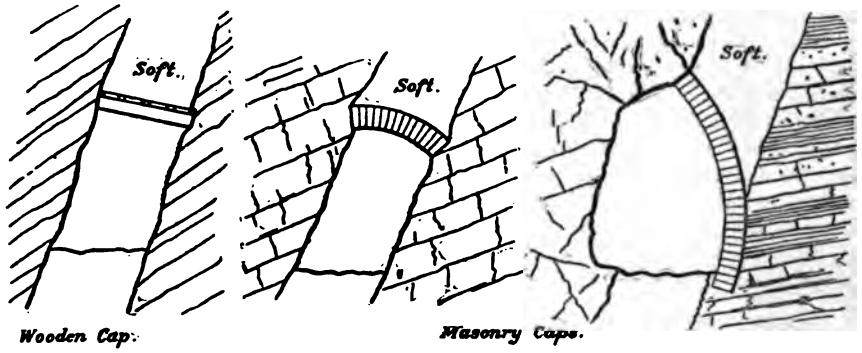
[2] H. Bauerman on coal mining.

[3] Page 1052.

[4] Cf. Mr. Clarence King's remarks on economy, p. 1031.

123° F., and though this is an exaggerated instance of the combination of moisture, warmth, and a comparatively stagnant atmosphere, it illustrates by figures the conditions to which timber in mines is subjected, especially poorly ventilated mines. The first cost of timber and the frequent repairs it requires have caused mining engineers in Europe to use masonry or even iron in their shoring. As illustrating the difference, several cuts from Mr. Inspector Foster's work on mining are given.[1]

When the lode in metalliferous mines or the bed or seam in coal mines is wide other measures must be taken. The methods are in general two. The first is to excavate, so to speak, streets in the bed after the manner that a city on the rectangular plan on which Philadelphia is laid out, then to attack the blocks of coal that support the roof. The other is to leave a wide ridge of coal through the length of which a main tunnel is driven, and from the sides of this offshoot-tunnels are opened, piercing the ridge. At the outer end of these offshoot tunnels the whole body of coal is removed and carted back to the main passageway. As the work advances from the outer end of the offshoot tunnels they are continued by protecting them from the matter accumulated by the pealing off of the unsup-



ported roof on both sides of the ridge of coal which protects the main tunnel and the offshoots to the edge of the ridge. It is not necessary to dwell upon the virtue of being chronically apprehensive in such situations where familiarity indubitably breeds recklessness.

The statutes of many States contain excellent provisions regarding the protection of life in mines.[2] The accident in the Hartley colliery, in England, upon which occasion the beam of the pumping engine fell into the shaft and closed it

[1] It is understood that the reclamation and anchorage of the moving sands of southwest France by planting pine trees (*Pinus maritima*) upon them by the government, has resulted, now that the trees have grown, in the sale of "props" to the English mines, the forest being replanted as the trees are removed.

[2] By the act of Congress (chap. 546, Rev. Stat.) of 1890-91, to provide regulations and inspection for coal mines, which are by far the most dangerous, the following rules are laid down in a general or abstract sense:

1. Owners, lessees, or managers of coal mines having an output of 1,000 tons a year shall provide at least two shafts, slopes, or other outlets (in addition to any furnace shaft), which shall be separated by natural strata of a thickness of not fewer than 150 feet, so that distinct means of ingress or egress shall always be available to the persons employed in the mine.

2. When a depth of 100 feet has been reached in any coal mine, not fewer than 55 cubic feet of pure air per second, or 3,300 cubic feet per minute, shall be furnished to every 50 men at work in the mine, and in like proportion for a greater number, which air shall, by proper appliances or machinery, be forced through such mine to the face of each and every working place, so as to dilute and render harmless and expel therefrom the noxious gases, and all workings shall be kept clear of standing gas.

3. A metal speaking tube from the bottom to the top of the shaft or slope shall be in all cases

so completely that before it could be removed the whole body of persons in th mine had been starved to death, caused Parliament to pass a law requiring tw shafts, at some distance apart, instead of one, divided into two compartment This provision has emigrated to America.

IMPROVEMENTS IN MINING MACHINERY.

The best though not the cheapest instrument in excavating ore in subterranea mining is the skillful miner, and all "improvements" in mining machinery ar directed on the one hand to supplanting him or to enabling him to work more exp ditiously by removing the accumulated water and gases that impede or woul eventually prevent his working at all, and on the other hand to the economica transportation of the product of his labor to the places of assortment and fina deposit. Explosives and the drill are generally employed in operations for metal liferous ores, but the inflamable and dust-laden nature of the atmosphere of man coal mines renders the use of explosives dangerous.

Few forms of manual labor surpass in their arduousness of muscular exertion in their painful constraint of attitude and movement, in their liability to acci dent and death, and in their habitual and unavoidable filthiness, the toilsome strug gle of the industrious, lonely pickman, whose hard lot has consigned him to pas his working hours hewing with violent efforts into a hard seam of coal in a badl ventilated mine.[1] Where the coal seams are thick, and the miner has 5 or 6 feet o thickness to smash at, a bungler by sheer brute strength can manage to make a fai wage. But such men are dangerous to have in a mine. It takes a man years t become acquainted with all the indications of danger. "The eye, the ear, th sense of smell, and the very nerves of the experienced man tell him when dange is near. If it were otherwise the accidents in mines would be tenfold more numer ous than what they are."[2] In excavating other minerals than coal, however, th dangers and the discomforts are possibly fewer.

THE MACHINE ROCK DRILL.

The rock drill, it is claimed, is distinctively an American invention. It embodie more newness in comparison with its volume and weight than any other machin of equal importance. André, in his work on Coal Mining, states the requirement of such a machine to be—

1. A machine rock drill should be simple in construction and strong in ever part.

---

provided. An improved safety catch shall be provided, and a sufficient cover overhead shall b provided on every carriage used in lowering or hoisting persons. Only experienced and com petent men shall be placed in charge of hoisting apparatus, and the number of persons to b admitted at one time in the carriage shall be specified by the inspector of the mine hereafte described.

4. There shall be appointed by the President as mine inspector for each organized or unorgan ized Territory (practically Alaska) a person who is either a practical miner or a mining engi neer, and who shall not be interested in the operation of any mine in the Territory whil serving as inspector. He shall have right of access to and of inspection of any coal mine in th Territory, but in performing this duty he shall in no way impede or obstruct the working o the mine, and the owner shall furnish him facilities for performing his duty. He shall report a least once a year upon the condition of the mine and the provisions for the health and safet of the miners, as detailed above. In case of fatal accident, a full report shall be made by th management of the mine to the inspector in writing.

5. Failure to comply with the provisions of this act is punishable by a fine of $500 or less sum and as a cumulative remedy, a court of competent jurisdiction may enjoin the working of th mine until the law is complied with.

NOTE.—Any organized Territory certifying a copy of its laws for the safe operation of mine within its Territory shall be relieved from the incidence of the Federal law.

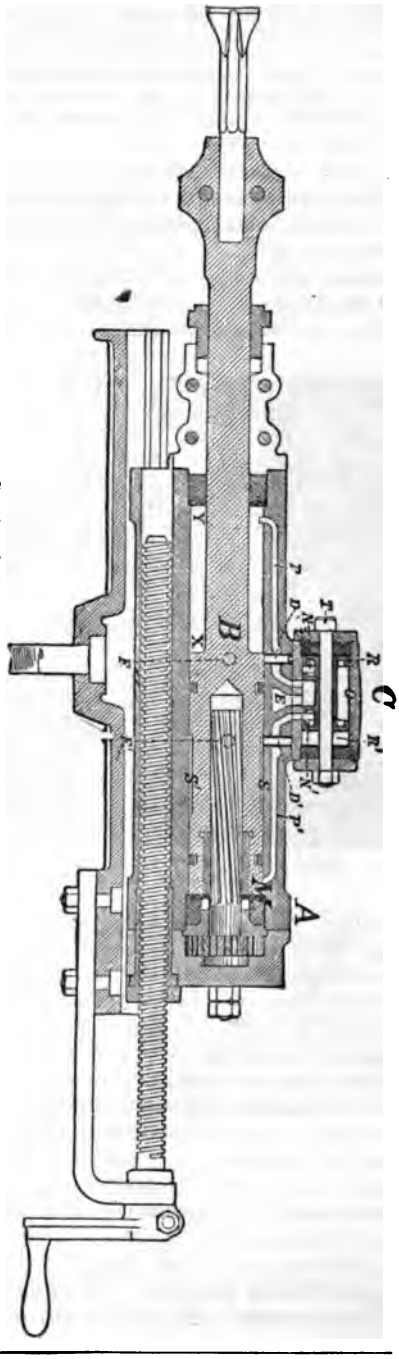
2. It should consist of few parts, and especially of few moving parts.
3. It should be as light in weight as can be made consistent with the first condition.
4. It should occupy but little space.
5. The striking part should be relatively of great weight and should strike the rock directly.
6. No other part than the piston should be exposed to violent shocks.
7. The piston should be capable of working with a variable length of stroke.
8. The sudden removal of the resistance should not be liable to cause any injury to any part.
9. The rotary motion of the drill should take place automatically.
10. The feed, if automatic, should be regulated by the advance of the piston as the cutting advances.

J. J. Couch, of Philadelphia, first patented, in 1849, a percussive rock drill embodying some of these features. In the same year, but a little later, Joseph W. Fowle, of Boston, patented and built a drill, the first one that had ever been introduced where the drilling tool was attached directly to the engine or was an elongation of the piston rod. Subsequently Charles Burleigh constructed a drill on Fowle's patents, embodying important improvements. Since then, Ingersoll, Wood, Githens, and Sergeant have endeavored to bring the drill more nearly to André's dicta. All the early drills were what are now known as "tappet" drills; that is, the movement of the valve was effected by "tappets" projecting into the cylinder and struck or moved by the piston. But the "tappet" construction does not follow one of the most important conditions of a perfect rock drill in that a part other than the piston is "exposed to violent shocks."[1] In 1873 Henry C. Sergeant abandoned the idea of the old tappet-moved drills and designed the Ingersoll Eclipse drill, which is described by its manufacturers as follows:



Sectional view of "Ingersoll" Eclipse Drill.

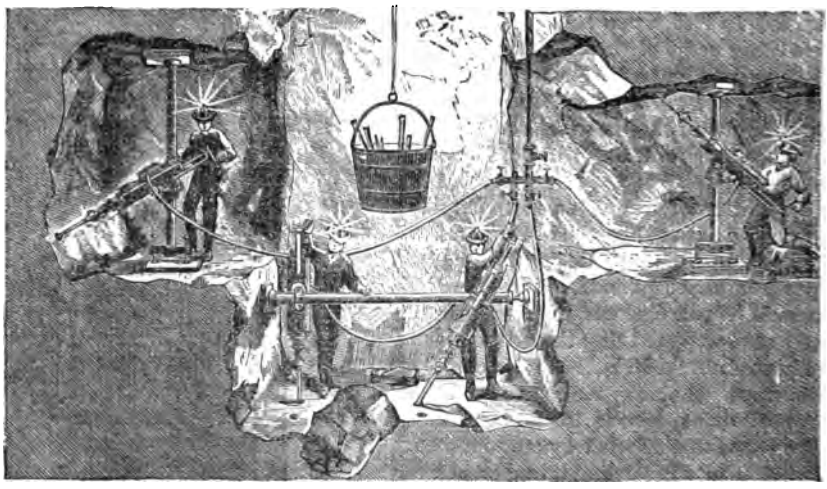
The Ingersoll has a variable piston stroke, which is of utmost importance in a rock drill. In starting a hole in hard rock the stroke is shortened by simply turning the crank, thus feeding down the bit close to the rock. A hole can be started with a short stroke in one-half the time required with a full stroke. Another advantage of the variable stroke is that it enables the drill to

[1] William L. Saunders.

work loose in seamy or broken holes and to loosen the mud in muddy holes. Th drilling machine has only two quick-moving parts—the piston and the valve—an no part except the piston is subject to violent shocks. The blow struck is un cushioned, for the valve does not move until the blow is delivered, which is thu struck on the rock with full force, the machine not using steam or air expansivel but at full pressure in the blow and the recovery. Danger of breakage is ove come by elastic buffers at both ends of the cylinder. The machine is compari tively light, and is equally effective in both wet and dry holes. The drill may b run either by steam or compressed air, and may be operated attached to a tripo or a shaft or a quarry bar.

A very important feature, it is claimed, is the single-spool valve (C of the illus tration), which admits the motive power into the cylinder (A) to move the pisto (B), which, being light, is itself moved back and forth easily by the steam or ai used in the drill.

The economy of rock drilling by machinery was at one time a mooted question Mr. G. C. André[1] (writing in 1876) speaks somewhat paradoxically upon thi matter. After mentioning the inclination of the miner not to work so "arduously"

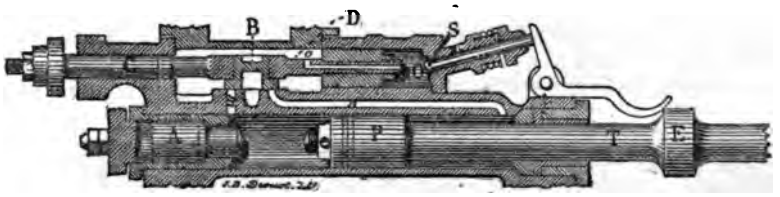


Positions of a machine drill in sinking, drifting, and stopping.

and his demands for more pay and combinations to obtain it, Mr. André remarks that "rock drilling is less a saving of money than of time;" for the "merit of the machine drill lies in its ability to concentrate the work of a number of men upon one point, or, which amounts to the same thing, to increase the amount of work executed in a given time by a given number of men, but the cost in most cases remains undiminished." It would thus appear, according to Mr. André, that as far as mining minerals is concerned, the machine saves time but not money. In sinking shafts or in tunneling where there may be a feverish anxiety to get at or through something the value of the rock-drilling machinery in hard rock is indisputable, but even in soft rock it is claimed by the manufacturers of the machine drills that "a mistaken idea is sometimes entertained by operators that in soft rock a hole can be drilled by hand before a power drill can be set up for the work. The conditions are exceptional when over five to ten minutes are required to set the bar (the supporting column upon which drill is mounted) in position, and once set, the hole is put down very rapidly. In sandstones a foot of 2-inch hole is drilled at the rate of 8 to 20 inches per minute, in limestones from 4 to 14 inches,

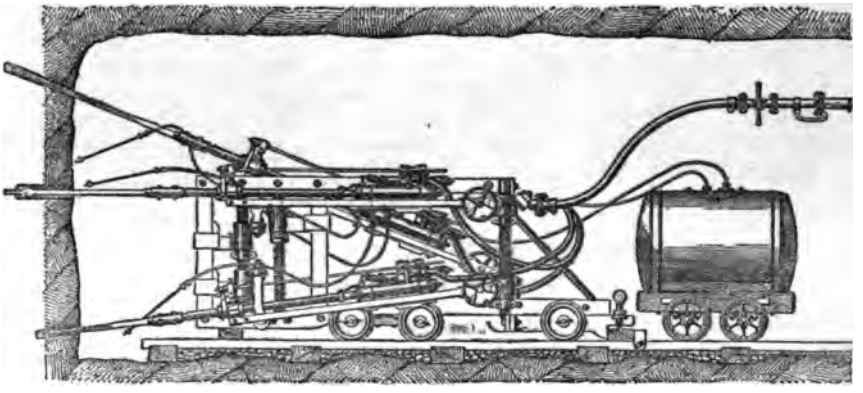
[1] Practical Treatise on Coal Mining.

and in granites from 2 to 8 inches, all running time. In some extremely hard, blocky materials the rate is less; but it is a rule that the harder the rock is to drill the greater is the advantage of machine over hand work. When drilling by hand the steel must be removed and the hole 'mudded' out every few inches. Power drills have a run of steel of 24 inches, and the hole cleans itself in most cases, often running to a depth of 8 to 12 feet without the use of a sand pump or swab-stick. Two drills may be mounted on one bar where the rock is hard and rapid progress is desired."



"Perforateur" of the Dubois-François drill.

A perforater, as the French call these drills, known in the trade as the Dubois-François, is highly spoken of. It consists of a bronze cylinder within which moves a piston marked P in the cut, the rod of which T carries the drill. A is a buffer in a chamber for compressed air serving to lessen the shock. Above the piston is the pathway through which the compressed air, admitted at the valve B, flows down through *m* and *n* to operate the piston. At C and D are secondary pistons, of which D is the larger and is pierced with an airway *o*O. The compressed air in the upper chamber striking both C and D drives them toward S, and the passageway *m* is opened, but the air flowing through *o* O fills the chamber S and the two secondary cylinders are moved back and the passageway *n* is opened for an



Rock drill called Dubois-François.

inlet and *m* is opened for an outlet. But the compressed air moving in through *n* to drive the piston rod T back causes E to operate the tappit so as to open S and let out the compressed air in the chamber into which the piston D works. The drill is rotated by an apparatus not here figured. As many as three or four of these perforators may be mounted and operated, as shown in the cut.[1]

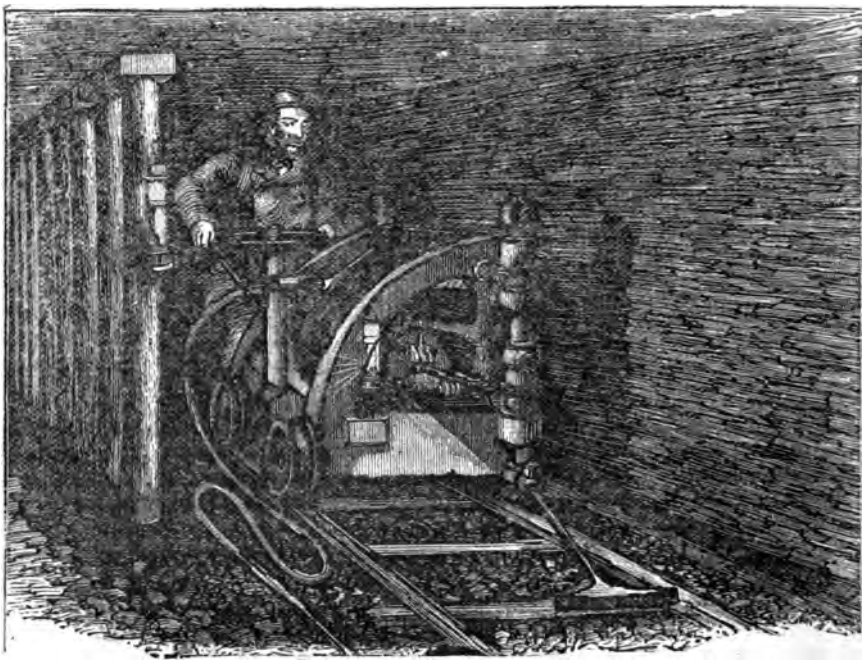
Undercutting Machines For Coal Cutting.

In the case of the rock drill the drilling of the holes is only the prelude to the ripping and shattering processes of exploding dynamite or blasting powder. The

[1] Les Mines, les Minières, et les Carrières par A. Badoureau, Ingenieur au Corps des Mines, et P. Granzier, Ancien élève de l'Ecole polytechnique.

machine must be set up, the holes bored, and then the whole apparatus must b removed from the effects of the contemplated explosion. Perhaps these feature of mining will never be entirely superseded by methods which occasion les delay, but for years unremitting efforts have been made to accomplish the worl of the pick with as little discontinuity in the work on the coal vein as possible and apparently there are several machines that will perform the work to a moderately satisfactory degree.

In 1863 a coal-cutting machine was introduced into the Ardsley and Newbottle collieries, England, upon the merits of which Prof. Henry D. Rogers was enthusiastic. This machine consisted of a large iron cylinder mounted on an iron truck (as shown in the cut), with a piston working as in a locomotive, except that, instead of communicating its in-and-out motion to a set of wheels, it caused an upright pillar

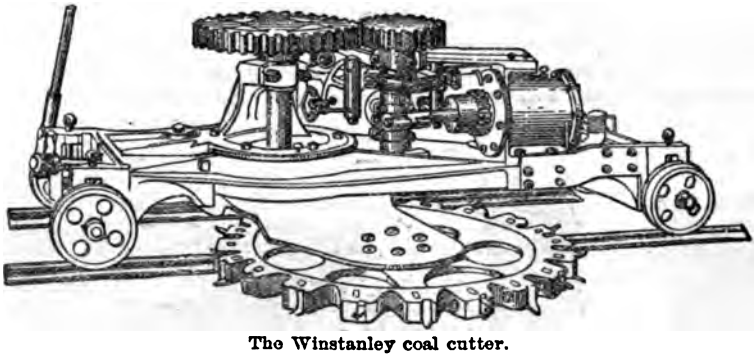


The West Ardsley coal cutter.

or tubular shaft, to the lower end of which was attached the handle of a massive pick, to make a quarter revolution or more.[1] Thus, instead of the miner resting upon his side, slowly undercutting the seam, upon which he works until the rumble of the setting coal warns him to desist, we have the pneumatic engine driving a ponderous pick, into the lower edge of the seam or beneath it at the speed of 120 strokes a minute, managed by one man comfortably seated on the carriage behind the cylinder, and refreshed by the escape of the air which struck the last blow. In this way one man pleasantly performed the dismal toil of fifteen or twenty able-bodied men. The success of the pneumatic picking machine being assured, Professor Rogers asks how will the miner who it is to supplant welcome it? And he finds no difficulty in coming to the conclusion that, in view of the deadly character of work in the coal mines, the collier will rejoice

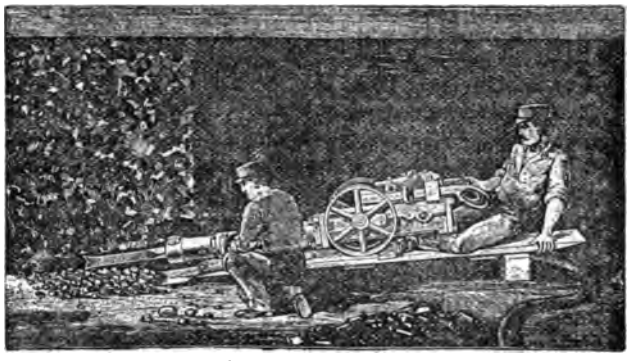
[1] Or, to express it technically, within the metal frame of the truck is a horizontal cylinder, fitted with a piston and trunk, and the piston by a connecting rod rocks an arm attached to a vertical shaft, which is provided below with a socket that carries a pick.

that heaven has sent a machine that will keep fourteen to nineteen men out of the mines. On the other hand, it has been estimated by that stanch friend of the miner, having been himself one, the Honorable Thomas Burt, M. P., that in coal mines alone 46,000 miners have lost their lives since 1861, the epoch of the perfection of the pneumatic picking machine of Yorkshire, to say nothing of the maimed and poisoned.



The Winstanley coal cutter.

The principle of the coal-cutting machine just described was a pick upon a handle moved by the partial revolution of an upright column, to which it was attached, as a spoke to the hub of a wheel. By 1875 a coal-cutting machine was described as in successful operation in which the pick was replaced by a circular saw operated, as before, by a pneumatic engine.[1] In a 4-foot seam it was said that the capacity of one machine would be 50 tons for each shift of ten hours, the work



The Ingersoll-Sergeant coal cutter at work.

of thirty or forty men.[2] This engine was called the monitor coal cutter, apparently from the revolving disk in the edge of which were placed the knives which cut their way into the surface of the wall of coal to the depth of 56 inches.

Among later inventions still are the Ingersoll-Sergeant coal cutter, the Yoch coal-cutting machine, and the Harrison. In the Yorkshire pick we have had the swinging motion imparted by the miner to his pick imitated by a machine. In the monitor engine we have had the tearing or abrading motion given by a rotating disk. We now come to the consideration of an instrument that pounds or drills out a groove by a blow delivered by a straight forward or thrusting motion against

[1] Mr. C. H. Waring as early as 1852 patented in England a machine of this description, worked by hand.

[2] P. W. Sheafer, C. E.

the seam. This machine, unlike the two types with which it is here compa requires no track. The illustration will sufficiently well describe its make-up mobility.

The diamond rock drill, despite its merits as a prospecting instrument, can be more than mentioned here, for we are considering methods of skillf exploiting a deposit, not of enriching deposit hunters.

The Subterranean Transportation of the Ore.

The ore being broken or blasted from its natural place, it becomes necessar remove it as economically but as quickly as possible. An old method of star it on its journey to the mule-drawn car is shown in the cut, but the mule po

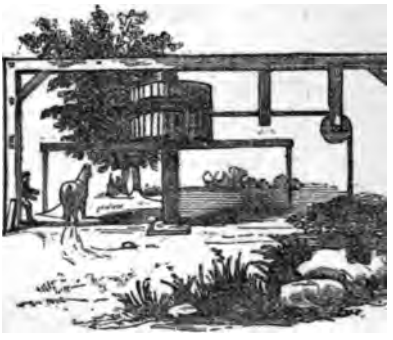
Pushing an ore car.



Whim.

which was formerly the great motor of the mine is now being supplanted by locomotive. At first this innovation was a mere form of the surface engine, its disadvantage was that it vitiated the atmosphere of the mine. The structors of this form of locomotive have now engaged in the constructio motors operated either by electricity or compressed air.[1]

When the level upon which the deposit is being worked does not open upon side of a declivity, it is very evident that the transported product of the m must be lifted to the surface of the earth. This was formerly accomplished very primitive way in Spanish America by the human back[2] and at the co mines of Michigan by a contrivance called a whim.

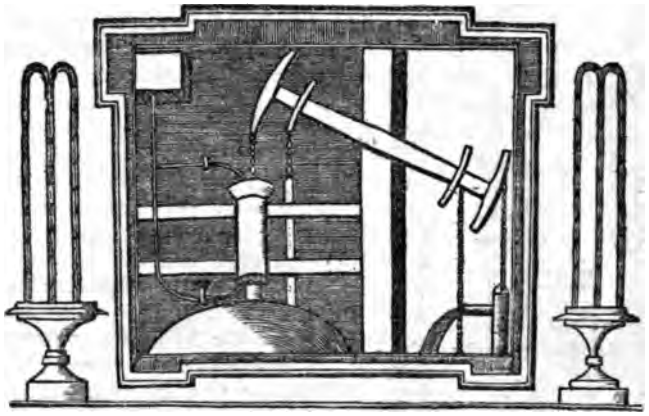
[1] In the August 18, 1896, number of the Scientific American, p. 136, there is a photogravu a "new-type" mining locomotive operated by electricity, built by the Baldwin Locom Works and the Westinghouse Manufacturing Company for the Crozer Coke and Coal Comp

[2] The tanateros of Honduras are a class of workmen employed to bring up ore in sacks f the bottom of the mine. They climb nimbly up the slippery escaleros (the apology for a lad

Compare with the methods represented in these illustrations of the lifting apparatus of the Spanish and Anglo-American mining engineers of 1850 the lift of any large building equipped with an elevator or the drums in the power house of any system of street railways with its wire rope built to resist abrasion. Indeed, endless chain or cable system is frequently employed in mines.

But the amount of mineral substance lifted out of deep mines that can not be drained by a tunnel or adit is far inferior to the amount of water that must be pumped out. The atmospheric engine that James Watt studied and improved into an entirely independent machine was merely a steam pump, the weight of whose pump rod mainly pulled up the piston that the atmosphere had pushed down into the vacuum artificially created beneath it in the cylinder in which it worked; and when Watt, in 1772, had changed the steam pump of Newcommen into the steam engine of our own day the first orders that were received by the new firm of Watt & Boulton were from the owners of coal mines.[1]

In all pumping operations the variation of the steam pressure and of load are frequent and unavoidable to such an extent as to be frequently attended with dis-



Reverse of a 2-shilling "waterworks note" issued by the city of New York in 1774, illustrating an improved Newcommen steam pump.—From Engineering.

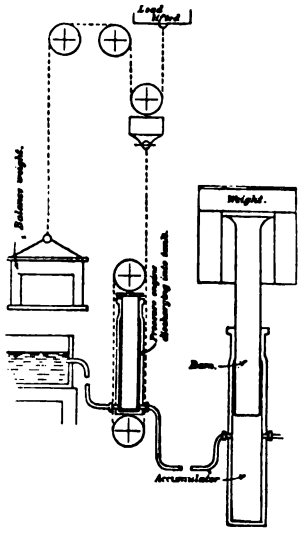
aster. To regulate the stroke, and especially to prevent as far as possible the jarring or pounding of the pumping machinery, a fly wheel has been attached to lifting and force pumps worked by power generated on the surface. The fly wheel is intended to stop the stroke or to slow it down when nearing completion. Similar efforts to regulate the stroke of the forcing class of pumping engines, which are placed at the bottom of mines, are apparent in the case of the Worthington engines and the isochronal pumping engines. But it is believed that eventually the system inaugurated at the Comstock mine some years ago will supersede the direct action of the steam-driven piston upon the pump rod or plunger. It seems paradoxical to lift water out of a mine by dropping water into it through a pipe, yet Mr. Joseph Moore, availing himself of the invention, called an accumulator, of Sir William, now Lord, Armstrong, conveys the water (and with it the accumulated hydraulic pressure) from the surface where the steam engines that feed the accumulators are, to hydraulic engines working plungers fixed almost half a

represented in the illustration) with a load of 125 pounds on their back (in 1855). Mr. Darwin says that the Chilean tanatero brings up as high as 200 pounds from a depth of 450 feet, living entirely on boiled beans and bread. Voyage in the *Beagle*, p. 283.

[1] History of the Steam Engine, Thurston, also Lardner, The Steam Engine (1827), p. 66 of 1836, fifth edition.

mile down in the mine below, and thus forces the mine water in one column ov 800 feet high to the level of the Sutro Tunnel at the rate of 1,600 to 1,700 gallons minute. This was an important innovation in the drainage of mines; on a mu smaller scale, perhaps, compressed air may be made to operate plungers in t same way, as at certain collieries of Pennsylvania.[1]

In noting, even in the fragmentary manner here followed, it can not fail to l remarked by the reader that between the steam engine at the surface and the scen of excavation within the mine a secondary engine is coming into play. Th power some years ago first entered the field of industry, except so far as natu had abhorred a vacuum in connection with pump, as a carrier of small packages and lette from one part of a building or a city to anothe through pneumatic tubes. Now, as compresse air, it is drilling holes into the hardest rock, unde cutting coal and driving engines, and even unde certain "artesian" conditions lifting water wit out the aid of valves. The use of compressed ai as a motive power, says a writer in the Scientifi American,[2] on board a war ship (which is a sort o floating mine, it may be observed), presents sev eral advantages over steam or hydraulic powe which render it a powerful competitor. In pipe it is less dangerous than steam, especially durin an action, when a bursted or broken steam pip might prove terribly fatal, nor is it calculated t elevate the atmosphere to an uncomfortable degree and there are certain places, such as the turre crowded with men, and the steering below th protected deck, where the exhaust from the pneu matic engines would be a source of comfort. A compared with the hydraulic power the com pressed air (on shipboard) is cleaner, more conven ient, and wholly free from the discomfort tha arises from leaking water pipes and cylinders.



Diagrammatic sketch of hydraulic accumulator.

As to the possibilities of the great secondary motive power of the times, electric ity, in damp excavations and gaseous mines in competition with the pneumatic or, as it is called, the compressed-air system, it is not within the sphere of thi paper to speak, but it would appear unquestionable to assert that electricity as means of illuminating mines can never be superseded.[3] This advantage may off

[1] The important civil engineering function of the mining engineer in sinking his shaft throug water-bearing strata is omitted as not particularly special to mining engineering.

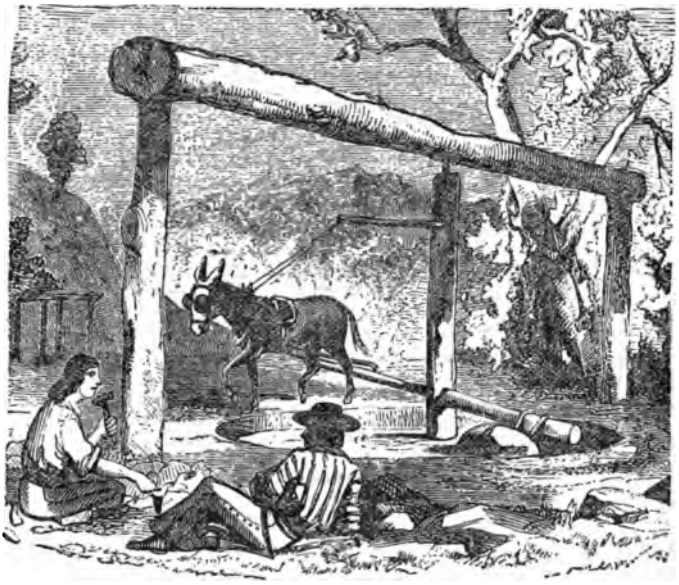
[2] March 1, 1897.

[3] Several years ago the Society for Mineral Industry (French) appointed a commission com posed of M. Fèvre, mining engineer, M. Place, director of the Rochebelle mines, M. Bessard director of the mines of Cessons, and M. Lange, engineer of the Rochebelle mines, to examin into and report upon the attempts made to construct electric lights adapted to the use of miners The experiments were made with four types of portative lamp, to wit: Pollak, Edison, "a trans portable but not portable," Breguet, and Stella. The report of the committee does not appea to have been conclusive, though the Stella lamp seemed to be preferred on account of its ligh weight and the perfection of its "appareil," which is, according to M. Georges Petit (Revu Scientifique, Tome XLVIII, p. 307), necessary, as "the danger (in coal mines) resides especially in the wires themselves." Let these be badly isolated by accident or ignorance and "a contact" may cause a spark and then an explosion. The light is not needed in the gangways, says M Petit, for even the horses know where to bob their heads though in the dark where the light i needed, as at the face of the wall, and the lamp from which it originated "must have the sam mobility of movement as the miner." It is useless, then, to dream of a dynamo installed abov ground feeding incandescent lamps below. It is useless to think the problem so easily solved.

set the hygienic properties of the expirations of a pneumatic motor, but it seems likewise justifiable to indulge in the expectation that "with increased knowledge as to the laws governing its transmission and use, with greatly increased efficiency in the methods of obtainining the air under pressure, and with the use of engines requiring but one-fifth of the original amount of coal required to drive the compressors, compressed air will rapidly take a leading part in power transmission. For mining and underground work it has advantages which can not fail to insure its increasing and continued use as its merits become better understood."

VENTILATION.

Whatever may be the fate of air as a motive power in operating the tools of mining, it is absolutely indispensable to the human machine. The State has interfered in this matter both at home and abroad,[1] and in several countries persons have been appointed to see that the law is executed. This inspection, however, does not always prevent disaster, and consequently is condemned by those for whose benefit it has been instituted. Mr. J. M. Forster, styling himself a miner, gives his ideas regarding mining inspection in England at the date of 1885 in very plain language.[2] Mining inspection, he says, speaking of coal mining, is useless unless it is thorough. It is of no use to examine the pit, shaft, furnace, and fan. It is the air ways and working places which need inspection, for it is in the far-away corners of the mine the ventilating current is weak, and there it is that great explosions have their origin. Now, how long would it take each subinspector to examine the 286 mines in his district? For the smallest, one day; for the largest, two or three days. In short, he can visit each mine once a year if he could devote his whole time to subterranean work, but this he can not do, for he is liable to be called away to the scene of some fatal accident.



El rastra.

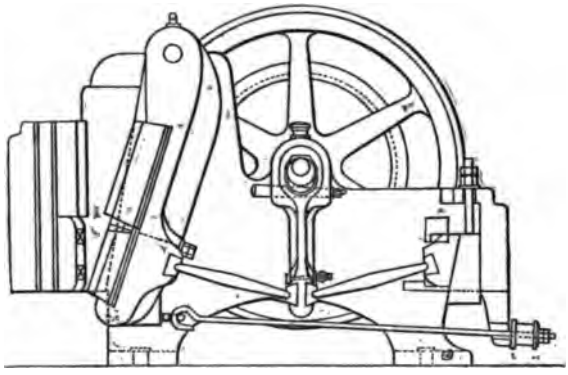
[1] See page 1041.

[2] Nineteenth Century, June, 1885. "Mining inspection a sham." In the issue of the following month a reply was made not materially invalidating Mr. Forster's criticism.

The old methods of dropping water down a tube into a water level to carry a current down into a mine, and the method of heating a column of air to carry a current up into the outside atmosphere have given place to exhaust fans or other machinery not so particularly special to mining as to call for mention. The greatest improvement is probably to be effected by a judicious study of the conditions of each mine, and not by inventions or even legislation.

METALLURGY.

The metals are mostly found in nature in chemical combination with oxygen, sulphur, carbon, and silicon, as has been stated several pages back, and, in addition, are embedded in matters which are called gangue. The first process, then, is to crush the metal, which is done in the case of the native or regaline metals in two operations. A Spanish-American method of conducting these is shown in the cut in which the person with the hammer breaks up the ore into nut-sized lumps, and a mule operating a "rastra" or drag slowly reduces the lumps to a paste or slime by the attrition of the two heavy stones strapped to the windlass, which drags them around in the pool; and it was said in 1859 that "the rastra is used with success at veins which have been abandoned as profitless for the modern



Blake stone breaker (Marsden).

quartz mill."[1] It is scarcely necessary to say that in the golden age of California this thoroughgoing but slow contrivance of Spanish inventive genius, when operated in California, was owned and managed by Mexicans.[2]

Among the very many machines that the last half century has produced to supplant the Mexicans, their hammer, their mule, and their drag, may be mentioned the Blake stonebreaker, which is said to have "rendered inestimable services to the miner, and to have constituted a most important step in advance in the art of ore dressing."[3] If the broken rock is to be still further divided until it becomes a pulp, the work is done by the old gravity process employed by the pile driver, whereby a weight is lifted and let fall, or by the direct action of steam upon a hammer, the weight of which is of comparatively small importance, or by an

[1] Harper's Monthly, Vol. XX.

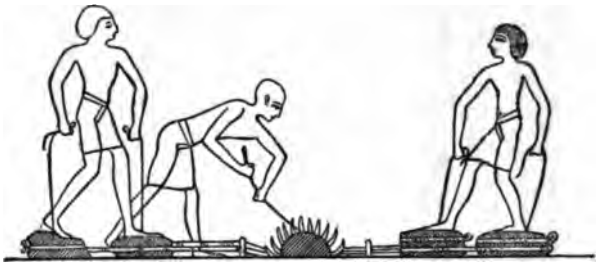
[2] Mr. T. A. Rickard observes in an article upon the "Limitations of the gold stamp mill" (Trans. Amer. Inst. Min. Eng., 1893) that "the use of a modern form of the arrastra at the Pestarena mill is quoted. The extraction, according to the report of the company, was 81 per cent in 1888-89, and 78 per cent in 1889-90. The loss of mercury in the respective years was 230 and 234 grams per metric ton, equivalent to about 7¼ pounds per short ton. The capacity of each mill was two-thirds of a ton per day. No doubt machines of the arrastra type will, in many cases, give the best conditions for promoting amalgamation; but, as compared with the stamp mill, most machines of the grinding class have a very small crushing capacity and consume a great deal of mercury."

[3] C. Le Neve Foster, D. Sc., (official) inspector of metalliferous mines in England.

Anglo-Saxon or quickened rastra process, whereby the pieces of ore are whirled around against each other and the bars of a cage, which is made to revolve with great rapidity. [1]

The size of the lumps broken off from the face of the wall, speaking of coal, has something to do with the amount of hand or machine labor required, both within and without the mine, to prepare it for commerce. Thus the hydraulic presses which force wedges into holes drilled into the seam of coal with the view of slicing it away without the use, in coal mines, of dangerous explosives, is said to bring down the coal in too large masses, for they required further breaking up. Possibly the same objection might lie against compressed air, which has already been applied to charging hollow cartridges of iron until they burst and rend the outer coal from the body of the seam.

The ore broken by the rock breaker may or may not be assorted by the hands of men or boys, and in Europe by children and women, but in either event two natural elements are called into play—one, gravity; the other, water—before the metallurgical processes are commenced. Take pieces of coal, "rock" or "gangue," and metals or stuff rich in metalliferous matter, and suspend them in water by moving them up and down, then the metals being heaviest will settle to the bottom, the gangue on top of the metals and the coal on top of the gangue. This



Smelting furnace of the ancient Egyptians and foot blast. Painting on the walls of a tomb in Thebes about 3,400 years ago. From Prof. A. Ledebur's Zur Geschichte des Eisens. (Ancient Egyptians, Wilkinson, p. 312.)

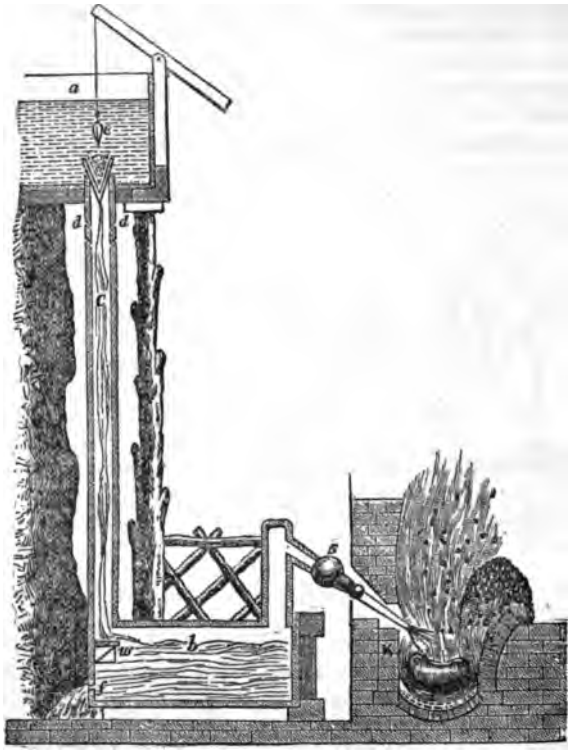
process is called "concentration" in the case of metals and "washing" in the case of coal slack. Formerly where the process was done by flowing water it was called buddling ("sluicing" of the California gold digger), and where done by agitating the pieces in a sieve (the panning of the Californians), is called jigging. Hydraulic mining of gold is jigging on an immense scale, the stream of a hose being directed against an auriferous bank, which breaks it down and washes away its less bulky contents. It will suffice to say that no improvements have been made upon the eyes of children and women nor the action of gravity or the use of water in the process of jigging save that it is now continuously carried on by appropriate machines, presenting many ingenious expedients to overcome obstacles in practice to the theory of "concentration."

The earliest representation of a blast furnace is painted upon a wall of a tomb in Egypt, which shows us the foot blast and possibly the bloom or mass of pasty iron.

[1] The Scientific American, September 26, 1896, gives the following popular account of the stamping machinery of the Calumet and Hecla Mine: "The stamp mills and copper-washing machinery used at the copper mines of Lake Superior have reached a high state of perfection. The advance in this particular which has been made there is wonderful. The early crude, iron-shod, wooden stamps that would crush a few tons of rock a day and hand buddles (separation of heavy metalliferous pieces from nonmetalliferous pieces by gravity in flowing water) have given place to large structures of stupendous machinery that crush 4,000 or 5,000 tons a day. Now 33 cents covers the cost of treating a ton of rock."

Another contrivance only lately disappearing from Spain and other parts of Europe is the Catalan forge, blown by a water blast or by a blacksmith's bellows.

This primitive rectangular open-hearthed water blast driven furnace was first changed into a sort of chimney by building up its sides and changing its form to that of a circle. Of nights the flames from such a furnace could be seen ascending 15 or 20 feet above its top. Eventually the heat thus wasted was utilized by closing the top and tapping the hot gases in the manner shown in the French furnace now pictured,[1] it being understood that such a furnace is charged with alternate layers of ore and fuel. Attention is called to the massive character of the masonry held together by iron bands and the rounded corners of the interior cavity.



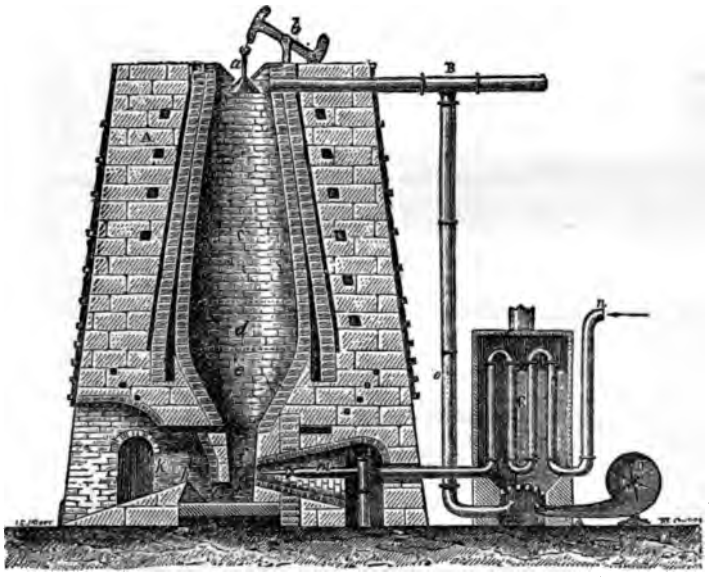
A Catalan forge and "tromp blast." (The current of air drawn into the pipe C by the trickling water falling through it feeds the tuyere S. From Greenwood's Iron and Steel.)

In the figure below given the hot gases are carried out of the furnace proper and emptied into a secondary chamber, through which a fresh-air pipe runs, where the gases are burnt by letting in atmospheric air, and the flame thus created heats the fresh-air pipes in the chamber, and necessarily the uncontaminated air being driven through them by machinery to the tuyère or blast nozzle. Through the invention by Sir Williams Siemens of a "regenerator gas furnace," this method of heating the blast, though an immensely important improvement, has in turn been antiquated as completely as the high furnace has antiquated the open-hearthed. As applied to the blast furnace, the Siemens furnace is called the Cowper or the Whitwell stove (there are a number of improvements), and as one can not

[1] On page 1057. From M. Gerardin's "Chimie."

be used continuously in connection with the blast it is necessary to have two, as shown in the engraving (p. 1058), which is taken from a work by M. Troost.

The Catalan open furnace, wasteful of iron and of fuel, and worked by a blast



Crosscut view of a blast furnace with a closed top and an arrangement for heating blast as it passes through pipe to furnace.

that was cooled by falling water, has thus, in comparatively recent times, been changed into a huge chimney, closed at the top, the gases of which are made to heat the blast of fresh air that is driven into the furnace to melt its contents. The

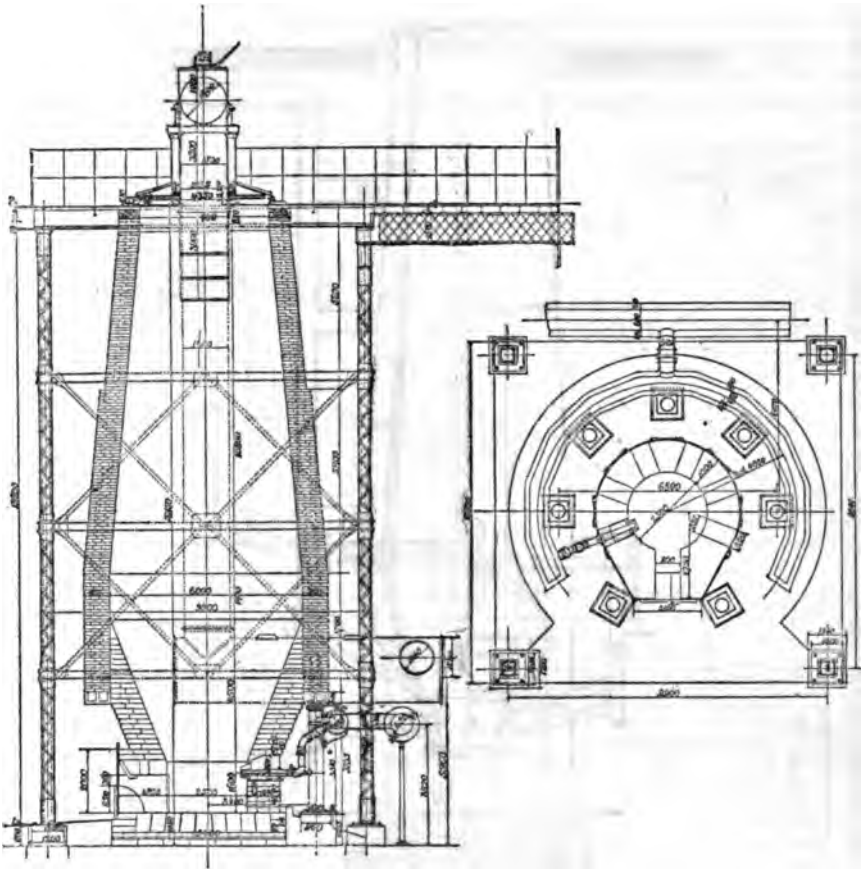
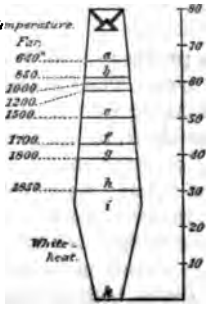
feet high and 16 to 20 feet across in 1861 now build them 90 to 100 feet high, with a diameter of 25 to 30 feet.[1]

The Germans have endeavored to improve the furnace by reducing the amount of weight that the upper truncated cone or reservoir throws upon the bottom



Blast furnace at Hörde, Westphalia, for fine-crushed ores.

cone or the "boshes." This has been accomplished by leaning the upper edge of the lower cone against the lower and pillar-supported end of the upper cone, as shown in the cut above, the whole being bound together by iron trestling, the



[1] The scheme representing the temperatures in a blast furnace is due to Sir L. Bell. The zone *a* contains the raw materials, ore, flux, etc.; in *b* the ore is partially reduced by carbon, and in *c*, where there is a dull red heat, the limestone added as a flux is decomposed into lime and carbonic acid. In the zone *e* carbonic acid oxidizes carbon from the fuel, forming carbonic oxide, and in *f*, which is a bright red heat, the reduced iron takes up carbon, forming pig iron. This action is continued in the lower zones, in which foreign oxides, such as silica and phosphoric acid, are also reduced, their bases uniting with the iron. In the zone *i* the iron is thoroughly fused, as well as the slag formed, by the union of the flux with the earthy matter. In the zone *k* the molten materials separate according to their specific gravities, the iron falling to the bottom and the lighter slag floating on top.

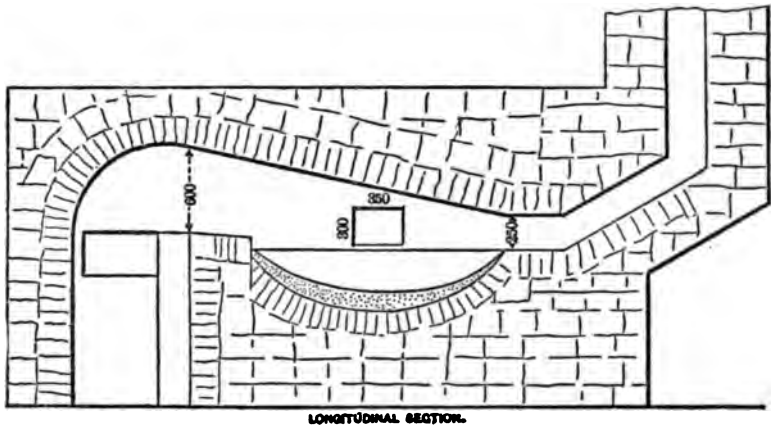
American Institute of Mining Engineers.[1] The walls of the entire body

furnace are of wrought-iron plates, and are double. The blast can be admitted at different levels or in the hearth itself. The blast, passing spirally around between the iron walls, is given a temperature of 300° to 500° F., and, by means of a system of dampers marked *t* on the cut, can be emptied into the hollow between the walls at certain levels. The furnace proper ends at the line of *g*. Below that is a movable hearth having holes through which the slag runs into a wagon.

There are two systems of smelting, namely, in a blast and in a reverberatory furnace, whose characteristics, and peculiar conditions, have been stated by Mr. Richard Pearce in his address on the Progress of Metallurgical Science in the



PACHAMANCA FURNACE

Dimensions in Millimeters: 1⅛ in. = 1000mm.

West, as follows, having reference, perhaps, to the complete reduction of the lead and copper contents of the gold and silver ores of the Cordilleran range:

	Blast-furnace system.	Reverberatory system.
Atmosphere	Reducing	Oxidizing.
Fuel	Coke, charcoal	Coal, wood.
Degree of concentration	Low: 6 or 7 in 1	High: 20 in 1 before separation of silver.
Per cent of base metal required to collect the precious metals.	15 per cent of lead.	3 per cent of copper.
Lime as flux	Necessary	Unnecessary.
Calcining pyritiferous ores	Should be complete	Not necessarily complete.

[1] By Mr. F. Lynwood Garrison, Philadelphia, Pa.

The old-fashioned reverberatory furnace in use ten years ago, with a capac of 10 tons per day and a ratio of fuel to ore of 1 to 1½, would stand no cha whatever in competition with the present style of blast furnace. But cert changes in the construction of the reverberatory within the last two years h increased the capacity to about 25 to 27 tons per day, with a ratio of fuel to ore 1 to 3. This, perhaps, is the highest record reached by reverberatory smelti except some work said to have been accomplished in Montana by introducing r hot ore into the furnace direct from the roasting cylinders.[1]

A primitive form of the reverberatory furnace, still used in Peru, is given in t cut. It is said that "the most recent development of the reverberatory furn resembles the earlier form in the construction of its bed, but is fired by gas p pared in an entirely distinct apparatus known as a "gas producer."

The regenerator furnace of Sir William Siemens has been spoken of when ill trating the utilization of the waste gases of the blast furnace. There the h gained by the operation of the "regenerators" in the Whitwell or other form

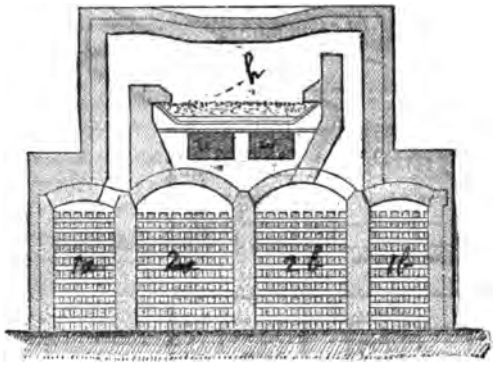


FIG. A.

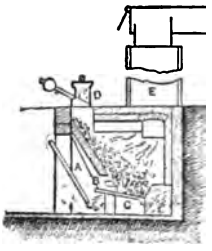

FIG. B.

FIG. A.—Vertical section of Sir William Siemens's regenerator furnace. The four chamb beneath the pan or furnace bed proper (*h*) are divided into pairs. They are open-worked bri work. In the *a* pair, 1*a* is used to heat the gas produced by the fuel, as shown in Fig. B, wh is called the producer. When the hot gases from the producer are let into 1*a*, cold air is let i 2*a*: the two currents pass up through the open brickwork and meet over the furnace bed hearth (*h*), where a fire has been kindled to ignite the mixture. The gaseous products of t combustion pass off and down through the *b* pair of regenerators, heating them. When th are hotter than the *a* pair, the process is reversed; and the furnace (*h*) being now thoroughly h the air and gas from 1*b* and 2*b* catch fire spontaneously on meeting above the hearth or bed (The furnace bed is made of iron boxes cooled by circulation of water (*w*).

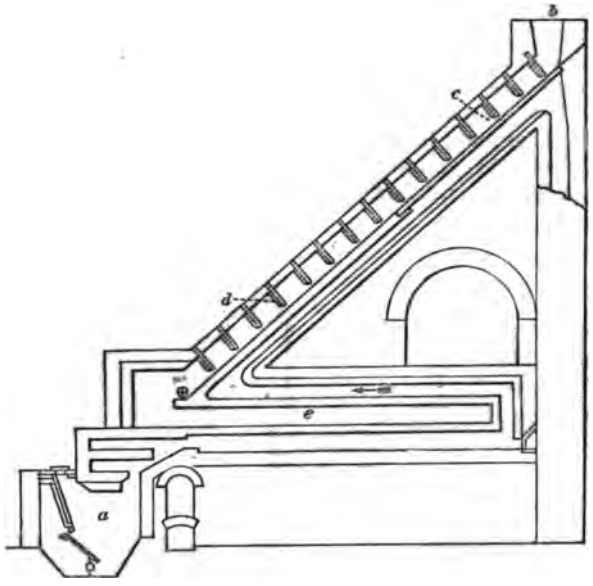
the Cowper stove is wholly a gain. But the original invention had in view gas producer as well as a gas regenerator. In the gas producer culm or slack, even sawdust, may be used, though soft bituminous coal is the best fuel. T inflammable chemical product of the combustion in the producer is principa carbonic oxid, called "air gas," and when this is subjected to a steam jet its c bon is hydrated and the product is called water gas; this, when burnt in the f nace proper or hearth in connection with warm, fresh air, bursts into flames a gives an intense heat.

The work of the mining engineer as a metallurgist is conceived in this article stop with the rendition of the metal, as that of the farmer does with the threshi of his wheat. The decarburization of iron in Bessemer converters belong to, o the forerunner of, a species of engineering which partakes more of manufacture what may be called commercial minerals, to distinguish them from the "e ments" of the books on chemistry, than to mining such oxides and sulphides the minerals as are found in nature. In this connection, however, two miner may be spoken of as having been first industrially prepared during the pres

[1] Address of Mr. Richard Pearce.

century. These are zinc, from its sulphur form of zinc blende, and aluminum, from its oxide form of bauxite.

Zinc sulphide,[1] being roasted in a reverberatory furnace to expel the sulphur, gives off sulphurous acid, which is valuable for bleaching, the refining of sugar, and the manufacture of ice, and as sulphuric acid is still more generally useful. Through the metallurgical skill of two Germans a furnace has been constructed by which some two-thirds of the sulphurous acid is conducted into condensing chambers and converted into sulphuric acid. A longitudinal section of this furnace is given.



Hasenlever and Helbig's furnace, by which two-thirds of sulphurous acid can be conducted into chambers and converted into sulphuric acid: *a* is a Siemans gas producer; *b* is the funnel through which ore is introduced and slides down the tube *c*, in which the partitions *d* make it spread out evenly in a thin layer; *e* is a muffle around which the gases ignited on leaving *a* pass on their way to the flue. The sulphurous acid is formed in the muffle, but "licks up" as much as possible of the sulphur of the ore on its way through the upper part of the partitions in the tube *c* until it reaches the last compartment at the top, where it passes off into a chamber.—Professor Dittmar in Encyclopædia Britannica.

Nor is this the only improvement in treating zinc blende, as that metal is now produced by electric deposition. The roasted ores are washed with wood ashes (lixiviated) in walled tanks coated with asphalt. The solution of zinc sulphate is then collected in the cistern (B), and when freed from iron, etc., is pumped into *c*, the "precipitating tank." The negative poles (*c*) consist of thin sheets of zinc; the positive poles (*d*) are of carbon, platinum, or lead. The zinc, being precipitated upon the sheets of zinc, copper, or brass, is easily removed, and the lye water, being rendered acid by the elimination of the zinc, flows away continuously through pipes (*e*), in order to be used for dissolving fresh masses containing zinc oxyde.[2] (See cut page 1064.)

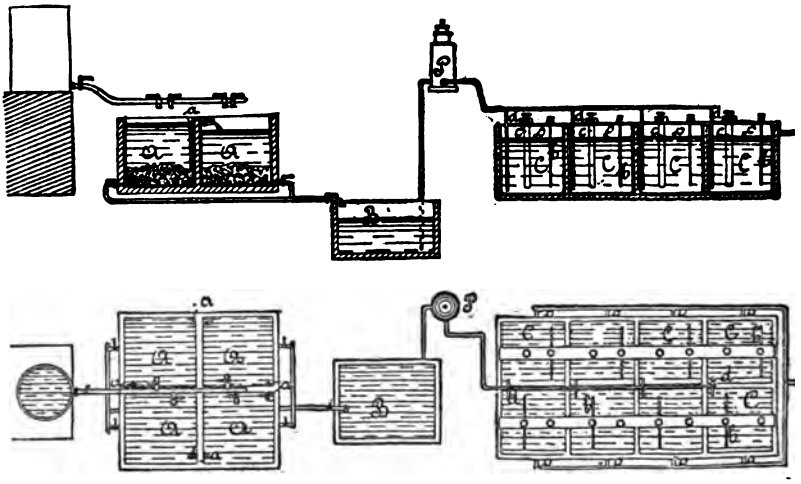
In this way the manufacture of zinc "has been revolutionized;" but though its manufacture is cheapened and the manner of its reduction changed, the revolution

[1] Quoting Professor Dittmar, mainly.

[2] Description of process and cuts taken from Chemical Technology, Wagner, translated by Crookes, New York, 1892.

has left the chemical qualities of the metal unchanged. In the fire proc after the ore has been desulphurized, it is, in one operation, put in a low furn in which are built a number of muffles, whence the metal is distilled over in chamber, from which it flows into the moulds. The ignorance of the metal gic property which zinc has of becoming malleable at a temperature of ab 266° F. was the cause of its being so long neglected. "The introduction of z among the useful metals," says a French professor, "is one of the most beaut conquests of our age." Perhaps such language is more appropriately applied the new metal, aluminum.

Davy, Brezilius, and Œrsted having failed to isolate aluminum, it was at obtained chemically by Wöhler by the medium of potassium, and in 1854 ma factured by Sainte Claire Deville, by the medium of sodium, in commercial qua ties. "Since that date," says Professor Troost, of the Faculty of Science, Pa "industry has been in possession of a new metal, which possesses remarka qualities, fitting it for many important applications in the arts," and, he may h added, for metallurgical synthesis in forming new industrial compounds. It not until within recent years, however, that the natural compounds of the m



could be attacked by agencies sufficiently economical in their operation to warr the production of aluminum. In 1879 Sir William Siemens patented his Siem electric furnace, which was the forerunner of that class of metallurgical agenc It consisted of a large crucible (connected with the poles from a dynamo), wh was placed in a vessel filled with charcoal. Iron, steel, and platinum could melted in such a crucible.[1] In 1885 the Messrs. Cowles, of Cleveland, obtaine patent for an electric furnace, and other inventors soon came forward. T electric metallurgy received a new direction entirely distinct from its use in metallurgy of silver and copper. Discoveries of this kind invite reflection. In preface as translator of the Baron de Joustrorff's "Practical Treatise on Me lurgical Chemistry" (Paris, 1891), M. Ernest Vlasto speaks of the change in French practice of that art in the following strain:

It is now nearly twenty years since I entered the great iron works of the Mes Wendel at Hayange. The function of the chemist in those days was far fr what it has since become. Then all that was expected of the laboratory was estimate of the amount of iron, silica, lime, and alumina in a given ore, or

[1] R. L. Packard, in United States Census, 1890; also J. Fleury, in Revue des Deux Mon L'Aluminium, first January number, 1893, p. 150.

amount of the ash in coke; hardly more than just that. Practical forge masters valued the form of a blast furnace by the look of the slag from it, and wrought and cast iron by the appearance of its fracture with a serene indifference to what its internal composition might be. Some years previously, indeed, forge masters had asked contemptuously, "What do I want with a chemist in my establishment?" and no one permitted himself to indulge in the extravagance of a laboratory except through vanity or for an advertisement. But the echo of the German cannon woke up our engineers. We began to study the steel guns of Krupp and the manufacture of this new steel. The war once ended, industrial metallurgy made a remarkable advance among us. We studied more—we studied what the English were doing. In short, we put ourselves to the task of analyzing a metal so that we could reproduce its character in any desired form.

In the way just described by M. Vlasto the possibilities of the synthetic mineralogy spoken of some pages back are evident.[1]

WHAT IS TAUGHT IN MINING SCHOOLS.

In the foregoing, after speaking of the mining-school curriculum from a theoretical point of view, we first briefly considered the manner in which the State has become connected with the exploitation of the mineral wealth within its borders, then the value of that wealth, and finally the improvement in the methods of treating it. In brief, it has been implied that a scientific study of mining with a view to a conservative treatment of the deposits with which nature has endowed the country as the basis of its industrial prosperity is well worth the study of our publicly endowed institutions of education. The selection of this social conception of mining engineering as a basis upon which to operate a school of mines may possibly be unfortunate, but the remark may be ventured that some conception beyond the mere personal aggrandizement of the pupil is absolutely necessary to create a successful school or system of schools.

---

[1] In the course of conversation in regard to the progress of metallurgical engineering, Mr. J. H. Blodgett informed a colleague of the Bureau of Education of the following circumstance, to wit:

An establishment converting pig or other forms of manufactured iron into manufactured articles of malleable iron was accustomed to draw its supply of the raw material from a corporation mining and smelting ore in Michigan. The manufacturing establishment in question had the habit of testing the fitness of the raw iron for the purpose of their manufactures. On an occasion of this kind it became evident that the structural or internal or chemical properties of the iron received was different from that furnished by the Michigan mining and smelting company upon former occasions. An inquiry was instituted which developed the fact that formerly the Michigan company had smelted their ores with ores obtained from the lands of another owner. Finding an apparently similar ore in their own land, however, they ceased to purchase the accessory from another and used their own instead. This produced an iron that was unfitted to the uses to which the manufacturing establishment designed to put it.

This memorandum was sent to the manufacturing establishment concerned with the remark that "this statement is thought to have some bearing upon a statement which may be made in print, that the examination of a metal, if rigorously carried out,—if analyzed in view of the services it is to be called upon to perform,—will eventually lead to the production of raw material suited to any given purpose." To which, in due course, the following courteous reply was received:

ROCKFORD MALLEABLE IRON WORKS,
Rockford, Ill., July 6, 1897.

MY DEAR SIR: Your favor of the 3d at hand. I remember the instance to which you refer in regard to the trouble I had with iron a number of years ago, and your statement of it is substantially correct. At the present time the conclusions of your friend are carried out in our line of business; that is to say, all iron we purchase on a guaranteed analysis specified in our orders for iron for our purpose, so that now each car of pig iron we receive is accompanied by a chemical analysis of its different constituents; in fact, nearly the whole pig-iron business in this part of the country is done in the same way. When we make a contract or order for pig iron, the percentages of the various constituents in the pig iron must come up to those specifications. The manufacturers of the pig iron buy their ores and fuel to get the results required by those to whom they sell. In addition to that, nearly every concern of any importance, especially in our line of business, have their own chemist, so that the raw as well as their products are analyzed and kept very close to the standard required. Each smelting furnace have their chemist, so that all ores, fuel, and flux are analyzed as used from day to day.

I think of nothing further that I could add to what I have above said.

Very respectfully,

A. D. FORBES, *President.*

J. H. BLODGETT, *Washington, D. C.*

Yet it is especially necessary and fair to say that this is not the argument for the study of mining in schools advanced by those who have attacked or defended the education of a mining engineer. "Let it be admitted," says one, "that the mining population is insignificant in number, that only 6,000 mining engineers are required in the United States; nevertheless the value of the material they produce makes them the most important element in the entire population."[1] Another specialist in engineering observes:

As for mining engineering, what is there about the ordinary work of the ordinary mining engineer which requires a different training from that of a mechanical engineer? Chiefly a certain amount of metallurgical and prospecting or sampling work. But to become a specialist in this kind of work a man should be a chemist and metallurgist at once and nothing else. * * * After a mine has been discovered * * * the chief work of the mining engineer is to open and operate the mine advantageously, and the knowledge and experience of a civil or mechanical engineer gives just the right preparation for this kind of work.[2]

To these very interesting statements may be added that of Professor Hoffman, of the Technical University of Berlin.[3] "We Germans are producing more scientific men than we can absorb, but we have the export trade in that commodity entirely to ourselves. Two or three years ago I was traveling in the United States, and wherever I went I found German chemists, and they were at the head of every industry to which scientific knowledge is applicable, chemical works, gas works, whatever it was a German was at the head of it."

However superior the Anglo-Saxon may be as an exploiter of nature and an inventor of labor saving or quickening tools, nevertheless in metallurgical or biological chemistry the genius of the race is not so pronounced as that of other nations to which belong a De Saussure, Dumas, Boussingault, Gay-Lussac, Liebig, Berthelot, and Pasteur, or more especially a Kirchhoff, Wöhler, St. Claire-Deville, Bunsen, Plattner, and Siemens. Men who have studied under such professors or their rivals are not turned back at Castle Garden, and American mining has fostered German mining education.

For one hundred and thirty-one years the Royal Saxon Mining Academy has been in existence, and we learn that the French school of mines was organized in 1778. Since 1851 there has been a not very successful attempt in England to provide such a State school. It, therefore, will be interesting to examine the characteristics of these schools to account for their prolonged vitality.

A comparative study of the programmes of the State schools of mines of the Kingdom of Saxony, the Republic of France, and the United Kingdom of Great Britain conveys the impression that the German school has avoided the tendency to turn out acute mining critics and the other tendency to make the school of mines an institution for training "science teachers" (i. e., school-teachers instead of engineers), or a college in which science is squarely opposed to literature as an educational agency. In Saxony the State owns the mines; in France the State in some degree is interested in them; in England the State merely inspects them by

[1] The Growth of American Mining Engineers and their relation to the Mining Industry.

[2] Engineering News, August 11, 1891, American Engineering Schools. But cf. also the answers received by Prof. H. S. Monroe, New York City, mentioned by him during a discussion on the demand for mining engineers in 1893. (1) The demand is small; (2) the course of a mining school is difficult; and (3) costs much time and money; and (4) it is possible to become a mine manager without going through a school; and (5) mining-school students do not come to schools from mining districts; and (6) other professions draw off students, particularly in the University of California, Washington University, Massachusetts Institute of Technology, and the School of Mines of Columbia College, where there are many parallel courses; and (7) prejudice against [college men; these answers seem to be from colleges], and (8) miscellaneous considerations (p. 2 of advance sheets of Transactions of American Institute of Mining Engineers).

[3] As quoted by the Right Hon. A. J. Mundella, M. P., in an address delivered as president of the Association of Technical Institutions, January 24, 1890, the remark being made personally to Mr. Mundella.

virtue of its police powers and the omnipotence of Parliament. It would be natural, therefore, to expect that the German Kingdom should organize its school so as to obtain engineers who mine, that the French school should turn out highly educated mining scientists or philosophers, and that England, where the miners themselves had asked for a school,[1] should confine its instruction to inspection for the protection of the life and the health of the miner.

The Royal School of Mines has had a checkered career since its establishment in 1851. By 1848 the violent opposition to Lyell's conception of the evolution of the crust of the earth had so far subsided that in that year he was knighted, eighteen years after the publication of his Principles of Geology. The effect of his two visits to the United States, in 1845 and 1849, upon American scientists is easily recognized in the letters of William Barton Rogers, so prominently connected with the Geological Survey and University of Virginia and the Massachusetts Institute of Technology,[2] to say nothing of the effect of broadening the horizon of the English geologist by his researches upon the wider and more massive field of North American formations—the Passes of the Mississippi and the alluvial plain the river is creating, the vegetable accumulations of the Dismal Swamp as illustrating the formation of possible coal beds, and Niagara Falls as a marker of time for the recent geological past. The effect in England must have been more intense, and a geological survey and a mining school were established. Later on the School of Mines became "Division B" of a "Metropolitan Science School," but by 1859 the Metropolitan School had disappeared in its Division B, and by 1871 the institution became almost entirely a normal school for preparing the science teachers then called for by the Parliamentary grants in aid of science. In 1881 the school was reorganized into the Normal School of Science and Royal School of Mines, and lately into an institution called the Royal College of Science, to which the "Royal School of Mines is affiliated."

Quite different has been the life of the French School of Mines at Paris. The person who is selected to enter that institution has already received two educations—that is, has been subjected to two species of instruction. First, he is instructed in his native and in foreign languages, including Latin and Greek, and in college mathematics. Having distinguished himself during this course, he is permitted to enter the École Polytechnique, where he receives his second education. The course of the École Polytechnique has been accused by one of its critics as drafting off the best brains of France merely to make learned engineers for the bureau service of the State, and has been defended as being a "great physico-mathematical encyclopedia," which is specialized as an educational institution, so as to develop the scientific sense or instinct and to furnish each pupil with the ideas that later on will serve him when engaged in professional work. In short, the school produces neither engineers nor officers. Its rôle is at once more elevated and more modest, and is to prepare students for the special schools, such as the civil-engineering school called the School of Bridges and Roads, the School of Mines, the Artillery School, where technical instruction is given.[3] In this École Polytechnique the student receives his second education, breathing an atmosphere saturated with mathematical language and generalizations of mechanical forces, and he is taught to theorize upon matter as philosophy theorizes upon intellect. Having passed successfully through this school, where the discipline is rigid and the instruction thorough in the highest sense, the students who are to become State mining engineers are selected out and appointed by the Government to the

[1] So the expression "mining districts" is taken.

[2] Life and Letters of William Barton Rogers, by his wife; Boston, 1897.

[3] Revue Scientifique, first volume of 1887; also M. Chandos's attack in same volume.

School of Mines or other engineering institution.[1] Turning from these generalities, let us consider more particularly—

THE ROYAL SAXON MINING ACADEMY AT FREIBERG.

Saxony is one of the twenty-four States of the federated German Empire. Of inhabitants it has little more than one-half the number possessed by Pennsylvania, and of area not quite one-eighth as much. Its mines furnish one-sixth the weight of coal and ore annually raised in the German Empire, or about 16,000,000 tons, which are valued at $15,000,000, being one-tenth of the value of the mineral product of the mines of Pennsylvania and one-eighth of the value of the products of the mines of all the Imperial German States. The Kingdom is old. It befriended Martin Luther and joined Gustavus Adolphus in defending the Protestant cause. Its compulsory school law was the first ever promulgated, and its industrial organization and system of education are unsurpassed. The Mining Academy at Freiberg is now one hundred and thirty-one years old, and seems still to be in vigorous life.

At the close of the year 1895 twenty-one persons were graduated from the Freiberg Academy of this little State that has about one hundred and fifty mines within its borders, mostly of iron, argentiferous lead, and coal. For the period elapsing between 1884 and 1896 the attendance at this academy increased 23 per cent, but as it fluctuated in a remarkable manner the character of the increase is given in diagrammatic form as shown on page 1069.[2]

It will be seen that the school has attractions for foreigners. From 1872 to 1892 it graduated half as many mining engineers as all the American schools put together, and the school discriminates as to the character of its diplomas. Thus

[1] *Course of the École Polytechnique (from among whose graduates the students for the École des Mines at Paris are selected).*

The course is of two years and is given under the following heads:

Analysis.—Differential and integral calculus. This course lasts two years. It is completed by conferences upon the immediate application of the subject studied. In addition, the students may be called upon to show their knowledge of the subject, on paper.

Descriptive geometry.—Different modes of representing bodies; study of the principal geometric surfaces. This course occurs during the first year.

Stereotomy.—Carpentry and stonecutting. Course occurs in second year.

Mechanics and machines.—Course of two years. Completed by designing of the parts of a machine.

Physics.—Thermodynamics, electricity, and magnetism (first year), acoustics and optics (second year). Completed by experiments.

Chemistry.—Metals (first year), organic chemistry (second year). Completed by experiments.

Astronomy and geodesy.—Course occurs in the second year. Completed by experiments.

Architecture.—Course is of two years. Completed by designs and projects.

Military art.—Course of the first year.

History, geography, and literature.—History of the political, military, and moral greatness of the principal States of Europe in modern and contemporaneous times. Course of two years and is completed by essays upon historical subjects.

German, drawing, coloring drawings, during two years.

[2] The absolute figures are:

	1885.	1886.	1887.	1888.	1889.	1890.	1891.	1892.	1893.	1894.	1895.	1896.
Saxons	54	53	46	50	50	42	34	34	41	43	39	41
Other Germans (Deutsche)	50	52	53	51	48	42	54	56	68	60	58	55

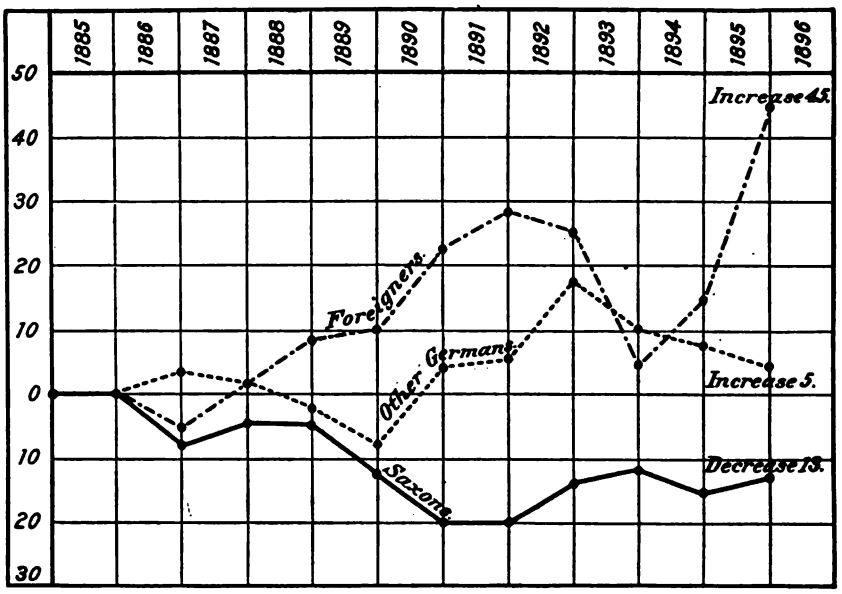
Total	163	164	153	161	166	153	170	178	193	168	171	200

the graduates in the mining-engineering course and in the metallurgical course were classed as follows:

	Mining course.	Metallurgical course.
Excellent (ausgezeichnet)	38	15
Good	103	75
Fair	74	49
Turned back	21	16
Total	236	155

It has been remarked above that there were 21 graduates from the Freiberg Academy in 1895. But these were not all indiscriminately dubbed mining engineers. Fifteen of them were graduated as mining engineers (Bergingenieur), 2 as



Change in the character of the attendance of the Mining Academy of Freiberg during 1885–1896.

mine surveyors (Markscheider), 5 as metallurgical engineers (Hütteningenieur), and 1 as Eisenhütten engenieur, or metallurgical engineer for iron. As this mining academy is intended to give a complete scientific education to the mining engineer and metallurgist, the student on entering must be 18 years of age and have graduated from an institution called a gymnasium, or a realgymnasium, or a high-grade scientific school, the value of the diploma of which is equal in quality, though not in quantity, to the degree of a "small American college."

The American Mining School.

In speaking of the mining schools of Europe no mention has been made of the fact that they are State-supported institutions. The importance of finding means to conduct the wars in which it became involved probably induced the first French Republic, in 1794, to create an "agency of mines," to study the questions relating to the mineral resources of France, possibly the first geological survey, and on the 1st of Vendemaire, in the Year 1 of those radical reformers, was issued the first number of the first Journal des Mines, which opened with these words: "Liberty

gives new forms as well as new virtues to those who fight for her. The soil of France is as rich beneath as upon the surface. It is time that the genius of Liberty should avail herself of the natural treasures which have been held in reserve for her. The Committee of Public Safety has become convinced that the interest of liberty requires that the mines should be vivified. An agency has therefore been established under the authority of the commissioner of firearms and gunpowder, which is to occupy itself especially with the subject." It was about this time that the French school of mines was firmly founded.

The geological surveys of the several States may have caused the creation of the American mining school, either by suggesting their value for educating engineers or providing geological surveyors. It is certain that the first attention mining engineering received from American schools was in the shape of courses in geology, mineralogy, and assay of mineral-bearing rocks, which was a course in "general science," as at the Rensselaer Polytechnic Institute, or the development of a civil-engineering course, as at several institutions, or even of "natural philosophy," as at the University of Virginia, where the course was described as an education for directors of geological surveys, their assistants, prospectors, and assayists. As the idea of a mining school began to be entertained, we find it in one case connected with the object of "promoting the interests of the university and the community at large," and that "the committee on the school is authorized to associate with themselves from time to time such gentlemen as are interested in the development of the mineral wealth of the country," and finally the positive expression, which the others may have implied, that the object of the mining school is "the advancement of the interests of science and in connection therewith to develop the mineral resources of the country." But the origin of the American mining school bears evidence of coming from Great Britain.

It has been mentioned that in 1854 a metropolitan science school had been founded in England. The plan of the school was this:

A. General division for those who desire a general knowledge of applied science. (Due to the desire of the Government to educate teachers competent to teach science schools outside of London.)
B. Mining and metallurgical division. (Due to the petition of the mining districts.)
C. Technical division for those who desire to engage in other business than mining and metallurgy. (Due to the petition of the chief manufacturing towns.)
D. Workingmen's division to afford instruction to workingmen by evening lectures. (Due to the rise of the "university-extension" idea.)

This English school was kept constantly in print, by the unquiet life it led, until in 1859 its name was changed to the School of Mines, and in 1862 reorganized with a view to specializing it as far as possible as a school of mines, the courses being (1) mining, (2) metallurgy, (3) geology. In the United States, about 1860, a prospectus of a Massachusetts institute of technology, to be a society of arts, a museum or conservatory of arts, and a school of industrial science and art, speaks of the Conservatory of Arts and the Central School of Arts and Manufactures of Paris and of the School of Mines and the Museums of Geology and Botany of London as worthy of reproduction in America. In 1862 the first committee of the Massachusetts institute was "on mineral materials, mining, and the manufacture of iron, copper, etc." In 1864 the department of practical geology, mining, and metallurgy was deemed so important that a separate pamphlet was printed outlining its course, and in the catalogue for 1871–72 the department of geology, mining engineering, metallurgy, and paleontology was unmistakably prominent. In fact, it is possible to surmise that the Massachusetts institute was about to be specialized, as far as possible, toward a school of mines, as in the case of the English school. It will be remembered that William Barton Rogers, who made the geological survey of Virginia, was the first president of this school as well as one of its founders.

In 1863 a proposition[1] was made to Columbia College, in New York City, to establish a school of mines and metallurgy. This proposition was adopted. A school of mines was opened in order "to furnish the means of acquiring a thorough scientific and practical knowledge of those branches of science which relate to mining and the working up of the mineral resources of this country and to supply those engaged in mining and metallurgical operations persons competent to take charge of new or old works and conduct them on thoroughly scientific principles." As finally settled upon in 1864–65, the course came to resemble rather closely that of the English school, as it consisted of (1) mining, (2) metallurgy, (3) geology and paleontology, (4) analytical and applied chemistry. In three or four years civil engineering was added to the course of this School of Mines, whose object was now stated to be to give "students the means of acquiring a thorough knowledge of those branches of science which form the basis of the industrial pursuits that are to play the most important part in the development of the resources of our country." In other words, the Massachusetts Institute of Technology, a general institution, seems to have tended to specialize into a mining school, and the Columbia College School of Mines, a special institution, seems to have very soon begun to drift toward a general engineering school. It is scarcely necessary to remark that during the seventies and eighties mechanical engineering and railroad surveying were offering great opportunities to students. As mining schools, neither the English or American schools have made great reputations. At least no foreign students flock to their halls for instruction.

An examination of the curricula of the present courses of mining engineering in the United States shows the following facts, to wit:

1. The course in "mining engineering," no matter what the name of the school may be, is always one of several courses in engineering, civil, mechanical, etc., taught in that school.

2. The course in mining engineering is composed of the same studies and they are taught in the same classes with the other generic kinds of engineering (mechanical, etc.) for the first and second year of the intending mining-engineering student's sojourn in the school.

3. The course in mining engineering is, during the first year of the course, more or less literary, though there are exceptions to this remark.[2]

4. The course in mining engineering specializes its curriculum to metallurgy, or to mine opening and exploitation, at the will of the student, save at the Massachusetts Institute of Technology, where the course is plainly a course in metallurgical chemistry, and at the School of Mines of Columbia University, where a fifth year is added to the course in order to give instruction in what may be called the strategy and tactics of mining operations.

5. The course in mining engineering is a four years' degree course, graduating either a "bachelor of science" or an "engineer," except that in the case of the Lehigh University and the Pennsylvania State College short courses have been introduced, and at the Michigan School, at Houghton, and at the University of California many special students are admitted.

The main distinction between the Saxon Academy, at Freiberg, and the American mining schools, outside of the personality of the institutions, to speak of them as though they were vital, sentient beings, is that the American school has a considerable amount of secondary or literary study mixed in with the technical study of mining. Compare the following statements of two American courses in mining engineering with the course of the Saxon Academy, set forth in Note D at the close of this chapter and, indeed, with that of the American school given in full in Note E.

[1] By Mr. Thomas Egleston, jr., subsequently the first professor of mineralogy and metallurgy.

[2] A very high authority in mining engineering and education has said on this topic: "In most of our schools, if not in all, the requirements for admission are too low. [It will be remembered that Professor Egleston is stating a fact, not making a charge of negligence.] The

NOTE A.

THE SOURCE OF CARBON.

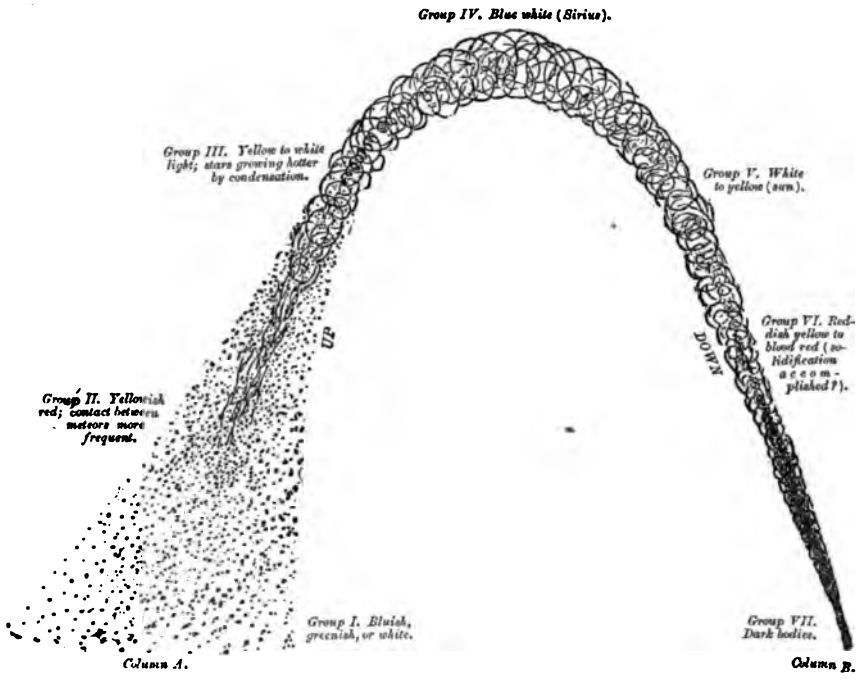
The formation in great variety of the compounds of carbon with the elements of water, that is to say, with oxygen and hydrogen, is the science of organic chemistry. It has been shown by experiments, which so far remain unimpeached, that the formation of cellulose, starch, etc., is done in the leaf and by the action of, let us say, chlorophyll. If there is no carbon (in the form of carbonic acid) present

---

student enters so badly equipped that from a year to a year and a half is expended in teaching him the mathematics and other preliminary studies which he must use in the later years of his course, so that any application of these studies must be confined to within a little less than half of the entire school training."—Thoughts and Suggestions on Technical Education, by T. Egleston, Ph. D. Advance sheets (apparently) of proceedings to 1888 Transactions of the American Institute of Mining Engineers.

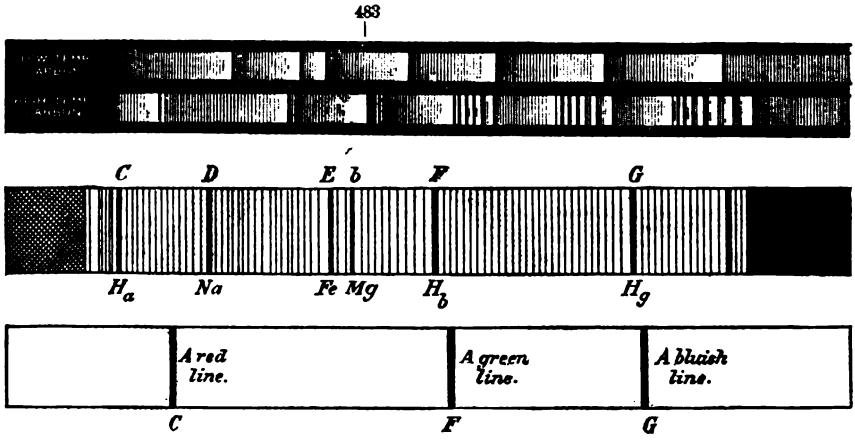
no growth will take place, no starch will be formed. Instead of being satisfied, then, with the dictum that the soil is disintegrated rocks, an inquiring mind might go back still farther and ask questions to which the spectroscope alone can give answer or suggest answers. In the "Chemistry of the Sun," and especially in the "Meteoritic Hypothesis," Mr. J. Norman Lockyer has given a place to carbon, or rather to the spectroscopic appearances of carbon, which make it as prominent in solar physics or chemistry as laid down in the Meteoric Hypothesis as it is in the organic chemistry of this planet. "The radiation and absorption flutings of carbon," says Mr. Lockyer, "afford the best means of establishing the connection between the physical and chemical nature of the various groups of [cosmical] bodies." These groups are arranged by Mr. Lockyer as shown in the cut, the more rapid ascent of Column A at Group III being due to a quicker generation of heat than the heat thus generated is dissipated in the falling Column B.

In this scheme Group II and Group VI are marked by the spectroscope as carbon stars. In Group II the condensing swarm of meteorites at the epoch, denoted by Group II, is not surrounded by an atmosphere-like envelope, if there is one, that is sufficiently thick to absorb the light of some state of heated carbon which



thus is emitted into space. Group VI, on the contrary, denotes a class of stars, each surrounded by a thick atmosphere or envelope which interferes with the perfect emission of light from some state of heated carbon, or, as it is said in the case of Group VI stars, shows "enormous carbon absorption." In short, a Group II star is a swarm of meteorites whose collisions are becoming more and more frequent as the swarm (under the influence, it may be supposed, of its vis viva, which, as such, must be a definite quantity determining at Group VII?) gathers itself together into a bunch, but radiating in the meantime less and less carbon light from its decreasing interspaces out into space, while a Group VI star is a solidifying globe with a red-hot crust of integrating rock surrounded by an atmosphere of unknown density and chemical composition. The spectra of many compounds of carbon with oxygen, hydrogen, nitrogen, chlorine, and sulphur, have been observed in the laboratories in this way, and it is found under certain conditions, which vary with the compound experimented upon, there are some markings, called flutings, which are common to all, which are not, however, uniformly interpreted by the learned. The main conclusions are that there are two systems of flutings which depend upon temperature only. At low temperatures (a coal-gas

flame into which pure oxygen is driven to make it hotter is a "low temperature") all compounds of carbon give a set of simple flutings. At higher temperatures there is a series of compound flutings, the brightest edges of which are at different places on the scale. At very high temperatures each compound gives the line spectrum (that is, black or bright-colored lines) of its constituents. Thus a molecule of marsh gas would give the spectrum of carbon and the spectrum of hydrogen, and carbonic acid the line of carbon and the line oxygen, the heat having broken up the molecule. Manipulation in the laboratory shows the difference between spectra of carbon at a low temperature and at a high temperature as follows: The line at 483 is not reproduced in the high-temperature spectrum, and is therefore taken as a sure indication of cool carbon because no fluting in the hot-temperature spectrum falls near it, which is not the case with the first two flutings at the right as you look at the cut.



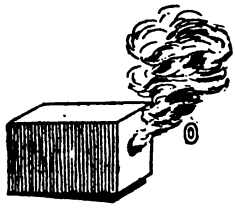
The upper spectrum is that of Sirius. It is an absorption spectrum, and the lines, which are black, cover the spectrum, such as an ordinary light ray let through the prism of the spectroscope would form, as though a grating had been let in upon the seven prismatic colors, the red being on the left. The lower spectrum is a laboratory or artificially produced affair, made by transmitting light through a tube containing hydrogen gas at atmospheric pressure; the red line at C, the blue-green line at F, and the blue-violet line at G shine out radiantly against the background of deadened prismatic colors, just as the black lines in the absorption spectrum of light from Sirius gridironed those colors in the upper illustration. Differences of atmospheric pressure or of temperature and of chemical combination may cause lines to move a little this way or that, though Mr. Huggins attributed the difference in place of the line F to the fact that Sirius is moving from us and we from it. It should be said that Mr. Lockyer uses the star α Lyræ instead of the more popularly known Sirius to represent his Group IV.

But what becomes of the carbon "phenomena" during the tremendous periods of time that must elapse during the course from Group II to Group VI? Group II shows flutes changing into lines; Group III stars show widening hydrogen lines as those stars get hotter; Group IV stars show "excessive hydrogen absorption," and their spectra are the simplest and their contents the hottest of all, while the Group V stars, such as our sun, show diminishing hydrogen, but greatly increased metallic absorption, chiefly iron, calcium, magnesium, and sodium vapors, which metallic absorption in Group VI is reduced, "while the carbon increases its intensity." "The reason why we have hydrogen absorption in such great excess in Group IV is possibly that most other substances, including carbon, have been dissociated (temporarily wiped out) by the intense heat resulting from the condensation of the meteoric swarm." The following representation of Dr. Huggins's photograph of the spectrum of Sirius, a popularly known Group IV star, will show that, though the whole spectrum is barred from one end to the other with "absorption" or black lines, that four lines are decidedly prominent, to wit: C, D, F, and G, the broad band-like bluish green line F being "characteristic" of hydrogen.

The condensation spoken of by Professor Lockyer has been reduced to a formula, and we quote Professor Newcomb's remarks in his astronomy to the following effect: "A curious law of cooling gases was discovered by Mr. J. Homer Lane, of Washington. If a globular mass is condensed to one-half its primitive diameter, the central attraction upon any part of its mass will be increased fourfold, while

the surface upon which the attraction is exercised will be reduced to one-fourth. Hence the pressure per unit of surface will be increased 16 times, while the density will be increased only 8 times. Hence, if the elastic and gravitating forces were in equilibrium in the primitive condition of the gaseous mass, its temperature must be doubled in order that they may still be in equilibrium when the diameter is reduced one-half. By losing heat the body contracts, but in contracting more heat is generated than what had to be lost in order to produce the contraction (p. 520). The value of this generalization is also vouched for by the high authority of Sir William Thompson, now Lord Kelvin.[1]

No one excelled the astronomer R. H. Proctor in his admiration for Saturn. He wrote a book about that planet and "his system," and quarrels with Laplace for his misconception of both in founding the nebular hypothesis upon them. In one of his essays he remarks: "Saturn's ring system is in reality a part as yet unfinished of his system of dependent bodies. It consists of multitudes of tiny bodies traveling in the same general plane. Hereafter, under the mighty forces of the planet's energy of attraction, this system of rings will be broken up to form two or three other worlds, akin to the eight satellites which already travel round the planet." Some interesting phenomena concerning rings on a small scale upon the face of the earth have been published by Prof. A. E. Dolbear, of Tufts College. They seem to show how a part of the atmosphere can be made independent, so as to be a form in the atmosphere.



In a box having a round hole in one end and a piece of cloth over the other place two saucers, one containing strong ammonia water, the other strong hydrochloric acid. The dense fumes may be expelled in rings through the hole by striking the cloth. The ring, once formed, consists of a definite amount of gaseous material or atmosphere in a state of rotation, made visible by the fumes. The ring moves forward in a straight line just as though it were a solid body, and if left to its own forces always holds itself up straight, as in the cut. It will push against anything that is before it; will, if moving parallel to a wall or table, move toward it and break up against it; but a light body like a feather or a thread will be apparently pushed out of the way in front of it, or in toward it if behind it. If two rings bump together at their edges, each one will vibrate with well-marked nodes and loops, showing that as rings they are elastic bodies, and that their period of vibration depends upon the rate of the rotation. If two rings be moving in the same line, one behind the other, but the hindermost moving the swifter, then the foremost one spreads itself, while the hindermost contracts itself and then passes through the first, both resuming their original form when without one another. If two meet in going in opposite directions, the smaller goes through the larger and may be held for a short time until the other has got some inches away. If two similar rings are formed at the same time, side by side, at a distance apart of an inch or two, they always collide, either destroying both or each may break at the point of impact and the opposite ends may weld together, forming a single ring, which will move as if it had been originally formed as one. In like manner three rings may become one, though sometimes the rings rebound at right angles to the plane in which they were moving; if moving crosswise, will bound up or down. The material of the ring rotates about the ring, but the ring does not rotate. (Matter, Ether, and Motion, by A. E. Dolbear, Ph. D., revised, enlarged, Boston, 1894.) It appears that Professor Tait first called attention to these singular phenomena.

NOTE B.

THE WHITE ANT—A THEORY.

A few years ago, says Professor Drummond in his Tropical Africa, under the distinguished patronage of Mr. Darwin, the animal in vogue with scientific society was the worm. At present the fashionable animal is the ant. I am sorry, therefore, that the animal whose praises I am about to sing is, as an ant, an impostor, as it is not an ant, but a termite; and so far from being in vogue, this clever but artful creature is hated and despised by all civilized peoples. Nevertheless, if I mistake not, there is neither among the true ants nor among the worms an insect which plays a more wonderful or important part in nature.

When we watch the farmer at work and think how he has to plow, harrow, manure, and humor the soil before even one good crop can be coaxed out of it, we are apt to wonder how nature manages to secure her crops and yet dispense with all these accessories. The world is one vast garden, bringing forth crops of the most varied and luxuriant kind, century after century. Yet the face of nature is nowhere furrowed by the plow, no harrow disintegrates the clods, no lime and phosphates are strewn upon its fields, no visible tillage of the soil improves the work on the great world's farm. Now, in reality there can not be crops or succession of crops without the most thorough agriculture; and when we look more closely into nature we discover a system of husbandry of the most surprising kind. Nature does nothing obtrusively, and it is only now that we are beginning to see the magnitude of those secret agricultural operations by which she does already all that man would wish to imitate, and to which his most scientific methods are but clumsy approximations.

A white ant hill of the Lake Region of Central Africa.

Now, in Central Africa, though I looked for them often, I never saw a single worm. Even when the rainy season set in the closest search failed to reveal any trace either of them or of their casts. Where, then, are we to look for the animal having the agricultural function—the tropical analogue of the worm? The animal we are in search of is the termite or white ant. In traveling through the great forests of the Rocky Mountains the broken branches and fallen trunks strewing the ground breast high with all sorts of decaying litter frequently make locomotion impossible. But in an African forest not a fallen branch is seen. The termites have cleaned them up. The insect excavates an elaborate system of subterranean tunnels, which mine the earth sometimes to a depth of many feet or even yards. The material excavated from these underground galleries is formed into the huge ant hills which form so distinctive a feature of the African landscape, extending for miles and arranged in mounds each 30 or 40 feet in diameter and 10 or 15 feet in height. The brick houses of the Scotch mission station on Lake Nyassa have all been built out of a single ant's nest. A supply of bricks as large again could probably be yet taken from it. The work of the ant is also a work of denudation. Nowhere as on the forest-clad hills of the great plateau between Lake Nyassa and Tanganika are the termites so masters of the situation. If it is the case that in these most elevated regions of Central Africa the termite colonies attain their maximum development, then the fact is of much interest in connection with the geological and agricultural function they seem to serve, for here precisely it is that the tiny head waters of the Nile and the Congo set their course. Herodotus, with equal poetic and scientific truth, describes Egypt as a gift of the Nile. Had he lived to-day he might have referred some of it to the humble termites in the forest slopes about Victoria Nyanza.

NOTE C.

SOLIDIFICATION OF AIR.

To those who are familiar with Berkeley's conception and proof of the immateriality of the world wherein he talks away the substance of matter by the most rigid logic, so that the only answer to it is to appeal to matter, it will be interesting to describe a machine by which the common air we breathe is converted either into a liquid or a jelly-like substance.

In Nature for February 6, 1896, there is an account of the machine used by Professor Dewar to liquefy oxygen, one of the two gases of the atmosphere, and the atmosphere itself. It appears that M. Olszewski, a French experimenter, had stated that air can not be solidified. To test this dictum Professor Dewar repeated his former experiments on a larger scale. His statement before the English Chemical Society runs thus: If a liter (1¾ pints) of liquid air be exhausted in a silvered vacuum vessel half a liter of solid air is obtained, which may be kept solid for half an hour. The solid is at first a stiff, transparent jelly, which, when placed in a magnetic field, has the still liquid oxygen drawn out to the poles, showing that the solid air is a nitrogen jelly containing liquid oxygen. Solid air can only be examined in a vacuum or an atmosphere of hydrogen, because it instantly melts on exposure to the air, causing an additional quantity of air to liquefy. It is strange to see a mass of solid air melting when in contact with the atmosphere, and all the time welling up like a fountain. So much for solid air, which is made from liquid air. Let us now see how liquid oxygen is made in what Professor Dewar calls a convenient apparatus,—"A simple arrangement for the laboratory, capable of producing 100 cubic centimeters of liquid oxygen, using liquid carbonic acid gas at 110° F. below zero for cooling." Here is the apparatus:

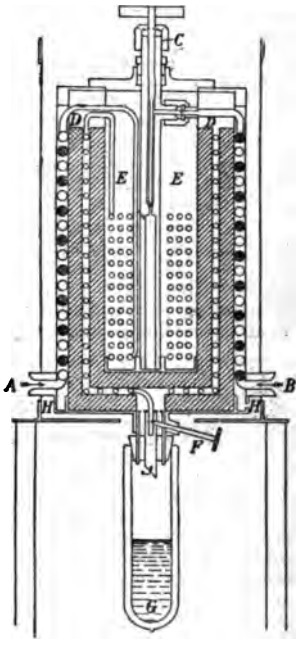

FIG. 1.—A, air or oxygen inlet. B, carbon dioxide valve. D, regenerator coils. F, air or oxygen expansion valve. G, vacuum vessel with liquid oxygen. H, carbon dioxide and air outlet. ○, air coil. ●, carbon dioxide coil.

NOTE D.

THE ROYAL MINING ACADEMY OF SAXONY AT FREIBERG.

The instruction at this academy is minutely divided into 64 topics, which are collected under 40 heads in the programme, taught by 17 professors or assistants. There are four courses in the school—one of four years for mining engineers, one for mining surveyors of three years, one of four years for general metallurgical engineers, and one of four years for metallurgical engineers in iron.

The first year of the mining engineering course has some resemblance to the "Physico-mathematical encyclopædia" of the École Polytechnique in France. It is preceded by a college education, but it is also preceded by a four months' course of a practical miner's course (practisch-bergmännischer Vorbereitungscurs) for those who desire to become students in the school in order that they may have the actual visual and practical knowledge for profitably following its courses. The studies of the first year are the calculus, descriptive geometry, theory of higher equations, spherical trigonometry, mechanics, study of metallic and nonmetallic substances, mineralogy, and practicum in crystallography, topographical drawing for mining engineers. The lectures on these subjects consume twenty-five hours a week during the entire school year, except the studies of higher equations and spherical trigonometry, which require four hours a week during the summer session. In addition, two hours are passed at descriptive geometry and two in the physical laboratory.

The second year the course begins to pass from the general to the particular. The calculus is now applied to the "quadrification, rectification, complanation, and curvature" of geometrical figures and physical problems. General physics

gives place to the study of the movement of a mathematical point, energy, dynamics and their applications, hydrostatics and hydronamics, geology and rock formation, mining literature and history, the more important minerals, surface and subterranean search for veins or beds, rock formation, exercises in classifying rocks, mineralogical and physical practicums, blowpipe analysis, and machine drawing. These studies occupy twenty-two hours of teaching a week and eight hours a week in laboratories or drafting room, except that classification of rocks occupies two hours a week only during the summer semester.

The third year, in addition to surveying and geodetic practicum, the following studies are introduced: The use and character of extractive machinery, ventilation, etc., under the name of special mining engineering, machinery taking the place of mechanics; veins and deposits taking the place of rock formation, the preparation of the ore for smelting, and finally general smelting. To these are added building construction and for coal "brikettiren," which is the process of compacting the dust of coal into bricks or "water-pressed stone." During this year machine drawing, principally of water and steam motors, is continued, four hours a week being devoted to it. Sixteen hours a week are given to lectures upon the aforenamed topics throughout the year, except that to labor-saving machinery are given five hours a week during the winter semester, and to the preparation of ore and coal, including coal-brick making, six hours are given during the summer semester.

The fourth year is almost entirely devoted to the consideration of practical sociological questions connected with the subject of mining, to wit: General law, mining law, mining and "metallurgical" statistics, capital, competition, labor, etc., hygienic conditions, but also mining geodesy and practicum, sketching mining buildings, exercises in preparing the ore or coal for commerce or smelting, and finally electrotechnic. Only four of the studies run through the whole year, to wit: Surveying, geodesy, hygiene, and electrotechnic, requiring seven hours of lectures a week, but to this must be added six hours a week of practice in mining surveying, four of sketching mining and metallurgical works, and two of electrotechnic. During the winter semester four hours of lectures are given to general law, one hour to statistics, and three to political economy. During the summer semester four hours are given to mining law and two to political economy.

NOTE E.

COURSES OF MINING ENGINEERING IN COLUMBIA UNIVERSITY, NEW YORK.

COURSES.

I. Excavation and tunneling—three hours first term. Professor Peele.

Excavation of earth—tools and methods; support of excavations; special methods for quicksand and other water-bearing material; steam shovels and other mechanical excavators: handling and transportation of excavated material; tables of comparative costs. Dredging—description of machines and methods for canal, river, and harbor work; handling of dredged material; costs of dredging. Explosives—black powder, nitroglycerin and its compounds, and other high explosives; their manufacture and use. Excavation of rock—hand and machine drills, methods of blasting, mammoth blasts, submarine blasting. Quarrying—plant and methods for quarrying different rocks. Tunneling—methods of driving and timbering; handling and transportation of excavated material; drainage and ventilation of tunnels; submarine tunnels; permanent lining of tunnels; accidents in tunneling; location of tunnels. Required of second-year students in the courses of mining engineering, civil engineering, and metallurgy.

II. Boring and shaft-sinking—three hours for three months, second term. Professor Peele.

Boring—methods and appliances for small depths and for deep boring; cable-tool or oil-well method; boring with diamond drill, for prospecting and other purposes; survey of bore-holes. Shaft sinking—methods and tools employed in soft material or in rock; special methods of sinking in water-bearing formations, quicksand; drainage of shafts; handling and hoisting of excavated material. Shaft timbering and other systems of lining employed in special cases. Required of second-year students in the courses of mining engineering and metallurgy.

II (A). Mining and support of mine excavations—three hours for one month, second term. Professor Munroe.

Theoretical considerations, methods of breaking ground in coal and metal mining, and support of mine excavations by pillars of mineral, by timbering, by masonry, and by rock filling. Required of second-year students in the courses of mining engineering and metallurgy.

III. Exploration, development, and methods of working—four hours first term. Professor Munroe.

Mineral deposits, characteristics of beds, masses, veins, and other deposits, and the irregularities and disturbances to which they are subject, as affecting the work of exploration and

mining. Examination and survey of mineral properties; relation of topography to geological structure; construction of maps and sections; and tracing of probable outcrops as a guide to exploration. Prospecting by ditches, pits, and deep boring. Development; choice of methods; location of openings. Working of deposits and support of excavations; methods applicable to deposits of different thickness, inclination, and character. Coal mining; vein mining; working of thick deposits and soft-ore bodies. Salt mining. Surface workings. Required of third-year students in the courses of mining engineering and metallurgy.

IV. Ore dressing and the mechanical preparation of coal—four hours for three months, second term. Professor Munroe.

The general principles and theory of dressing; preliminary operations; hand dressing; cleansing; crushing; jigging with and without preliminary sizing; slime concentration, and description of typical dressing works and coal-washing plants in this country and abroad. Required of third-year students in the courses of mining engineering and metallurgy.

V. Ore-dressing laboratory—one afternoon for two months, second term. Professor Munroe.

During the second term of the fourth year a portion of the time assigned to ore testing is devoted to the mechanical assaying of ores and coal by hand jigging and vanning. Required of fourth-year students in the courses of mining engineering and metallurgy.

VI. Mine engineering—two hours first term and one hour second term. Professor Munroe.

Extraction; methods and machinery; handling mineral in working places; underground haulage. Surface handling and transportation; arrangements for loading and unloading cars and vessels, and for storing of minerals. Mineral railroads. Common roads. Drainage; sources of mine waters; methods for the control and raising of water; dams; drainage; levels. Water supply. Ventilation; air of mines; mine gases; methods of ventilation; control and measurement of air currents. Accidents to men in shafts, levels, and working places; fire-damp and dust explosions; mine fires; inundations; rescue and relief of men. Required of fourth-year students in the courses of mining engineering and metallurgy.

VII. Mine plant—three hours first term and two hours second term. Professor Peele.

Descriptions and critical discussion of the machinery employed in hoisting, drainage, and ventilation; air-compressing plant; types of plant best adapted to different conditions; erection and care of machinery; accidents, breakage, and repairs. Lectures are given also upon the design of timber, masonry, and iron construction, head frames, hoisting cages, ventilating fans, mine buildings, and other portions of mining plant. Required of fourth-year students in the courses of mining engineering and metallurgy.

VII (A). Mine constructions—four hours for one month, second term. Professor Peele.

Building stones; brick; limes; cements, and concretes. Foundations in various soils; masonry and timber construction, with special reference to mine work; mine buildings; trestles. Required of third-year students in the courses of mining engineering and metallurgy.

VIII. Design of mine plant—five afternoons first term and four afternoons second term. Professor Peele.

The students are assigned problems involving the design and construction of mine plant, in connection with the development of a mine. This work supplements the lectures on the design of mining machinery, involving reading and study, and the preparation of working drawings, bills of material, specifications, and estimates. The work is done under constant supervision and advice in the drafting room. Required of fourth-year students in the course of mining engineering.

IX. Mine surveying—one hour second term. Professor Munroe.

This course supplements the practical work in underground surveying in connection with the summer school in mining. It includes the general principles of underground surveying, the construction of mine maps and models of mine workings, the measurement of contracts, and the location of lines for new work. Required of fourth-year students in the courses of mining engineering and metallurgy.

X. Administration and mine accounts—one hour second term, fourth year. Professor Munroe.

Administration, organization, and business management, mine accounts, and cost sheets. Examination and valuation of mines. Required of fourth-year students in the courses of mining engineering and metallurgy.

XI. The Summer School of Practical Mining is held in June and July, at some mine or mines selected for the purpose, in the vacation between the third and fourth years, and lasts five weeks. Professor Peele and assistant in mining.

The course of instruction includes six weeks' detailed study of the plant and methods of working at some important mine or mines; practical mine surveying; excursions to other mines and mining regions, and geological work, surface and underground. The course of study includes the subjects of shaft sinking, drifting, stoping, timbering, underground haulage, hoisting, mine drainage, ventilation, surface plant and machinery, mine buildings, shops, houses, water supply, drainage, organization, and administration. The students are divided into small squads, and assigned each day to a foreman or working gang of miners for the study of some definite object.

Graduate courses: Special courses consisting of personal instruction, reading, and experimental investigation will be arranged for advanced students according to their individual needs. These courses vary in difficulty and in the amount of time necessary, according as the student is a candidate for the degree of A. M. or Ph. D., and according as he pursues mining as a major or a minor subject. The following are suggested: Coal mining, two hours; ore mining, two hours; coal washing, one hour; ore dressing, one hour; examination of a mineral property of a mine, four to six weeks devoted to field and underground work, with conferences at professor's convenience; examination of a coal-washing plant or an ore-dressing plant with four to six weeks in a mill or laboratory with conference, special problems, etc.

CHAPTER XXI.

THE TENNESSEE CENTENNIAL AND INTERNATIONAL EXPOSITION, HELD IN NASHVILLE, TENN., MAY 1 TO OCTOBER 31, 1897.

Report of J. C. BOYKIN, Agent of the Bureau of Education and Chief Special Agent of the Interior Department.

WASHINGTON, D. C., *February 1, 1898.*

SIR: The Exposition at Nashville was held to celebrate the one hundredth anniversary of the admission of Tennessee into the Union. Tennessee became the sixteenth State on June 1, 1796, and the actual completion of her centennial was marked by elaborate commemorative exercises and by the dedication of the Exposition grounds. The opening of the Exposition itself was deferred until the following May, because it was impossible to complete the preparations on the scale desired in the time that intervened since the beginning of active work.

It was during the fall of 1893, when the Columbian Exposition was exciting so much admiration and emulation, that the idea of holding its like in Tennessee was first effectively advanced. The newspapers of the State at once took up the suggestion and during the following year the matter was widely discussed. Though several meetings more or less informal in character had been held, the real beginning of the enterprise was in June, 1894, when a convention of business men met in the capitol at Nashville. A temporary organization was then effected, a legal corporation formed, and the canvass for funds begun. Seventy-five thousand dollars were soon raised by private subscription, and Davidson County, in which Nashville is situated, promised $50,000 more. The effort to secure an appropriation from the legislature however failed, and without the prestige of State support the plan seemed doomed.

But the matter had gone too far to die without a struggle, and a mass meeting was called and held in July, 1895, to discuss the situation. Unexpected interest was developed, and the ardor of the speakers and the enthusiasm of those present were such as to put at rest all doubts as to the advisability of continuing the efforts for the Exposition. Other meetings were held, and the corporation was reorganized with Maj. John W. Thomas as president, Mr. E. C. Lewis as director-general, and a board of directors consisting of 100 of the leading men of the State. Thenceforward the work went on with redoubled energy and effectiveness, and no other serious setback occurred.

The legislature finally granted the funds desired; several counties in the State made appropriations; the city of Nashville donated $100,000, and the Congress of the United States passed an act admitting foreign goods for the Exposition free of duty, and provided for a Government exhibit to be housed in a building of its own, and appropriated therefor the sum of $130,000. There was therefore no lack of prestige so far as governmental recognition could give it.

It is worthy of note that from the conception to the end the purely commercial features of the Exposition itself were reduced to a minimum. It was explicitly stated in the prospectus that "the plan of celebrating this great event is not

intended as a money-making scheme, but aims at the higher and nobler e marking with proper dignity and display the end of an eventful century a recalling and keeping alive the deeds and names recorded to its credit." Nor these empty words. They were justified by the behavior and spirit that ma the conduct of the responsible officers in all their actions.

The location for the Exposition was well chosen. A racing park 2 miles w the center of the city, containing about 200 acres, was selected, and proved adapted to the purpose in view. The ground was slightly rolling, and th there were no grades sufficiently sharp to unduly tire pedestrians, the irregu ties gave good vantage points for the erection of buildings intended to be espec conspicuous.

The corner stone of the first building was laid with appropriate ceremoni October, 1895, but the real work of construction was not begun until afte celebration of the actual centennial in June, 1896.

The two largest buildings were devoted respectively to Commerce and Agr ture, the names being taken from the seal of the State of Tennessee. The large buildings were the Transportation, the Machinery, the Negro, the Min and Forestry, and the Government building, the Auditorium, and finally, the of all, the Parthenon. In addition to these there were a great number of sm structures, the principal of which were the Woman's, Children's, History, cation and Hygiene, and Railroad Terminal buildings. The names of mo these indicate the character of the exhibits in them. The Commerce buil contained the miscellaneous exhibits that have usually been classed unde head of "manufactures and liberal arts;" the History building contained reli historical value; the Parthenon was devoted to fine arts, and the Railroad Te nal building was used by several railroad corporations to display the resourc the territory through which they respectively pass.

All the buildings were covered with the composition known as "staff," an glare of the sun reflected from the masses of pure white in every direction pr very trying to the eyes on bright summer days.

The buildings were of considerable architectural beauty, and the appearan the place as a whole was very pleasing. Foliage plants and flowers were us great profusion on the grounds, and cool arbors and miniature lakes added t beauty of the scene. Especial attention was paid to illumination at night, in addition to numbers of arc lights distributed over the grounds, incandes lights were arranged "in rows, clusters, and circles" on the roofs of the build and on the bridges. About 10,000 lights were thus employed, and striki effective decoration was the result.

The plan of arrangement of the buildings was particularly happy. Upon most conspicuous point in the grounds was erected a full-sized model of most famous of architectural master pieces the Parthenon, and around that center the other principal buildings were grouped.

If there had been nothing else to make it so, the Nashville Exposition w have been noteworthy for the presence of the reproduction of the Parthenon. its principal dimensions and general appearance it was in accord with the orig and it not only gave an unsurpassed object lesson in Grecian architecture of highest type, but it led to discussions of the details and history of the orig that proved to be of great educative value. Nearly all the advertising circu sent out contained more or less information about the Parthenon, and the F Arts Catalogue began with a sketch of it, covering several pages, by the archi of the reproduction, Mr. William C. Smith, of Nashville. Nevertheless it see to me that the full significance of the undertaking was not generally reali and that not sufficient stress was laid upon it, even by the management of Exposition.

When it is remembered that the Parthenon was the finest specimen of ar

tecture that the hand of man has ever erected; that its decorations were the choicest productions of the sculptor "in whose works were established for all time the laws of beauty and sublimity in art;" that for a hundred years it has been the favorite study of archæologists, architects, and artists, and that while it has furnished ideas and inspiration for buildings innumerable, no attempt had ever been made before to reproduce it entire, then the value of the suggestion of Director-General Lewis and the importance of its execution may be the better realized.

THE PARTHENON.

The ancient city of Athens was built around a rocky hill about 300 feet high, which, after the custom of the Greeks, was called the Acropolis. The strength of this height from a military standpoint undoubtedly influenced the location of the city, and the Acropolis was in reality a citadel. But it became the site for some of the principal temples of the city, and early in its history it was devoted so fully to such uses that its military usefulness became entirely obscured by its religious aspect.

During the Persian invasion the Greeks were compelled to abandon the city and to take refuge in their ships. After the final defeat of the Persians at Platea, 479 B. C., the Athenians returned to find their fortifications and temples in ashes and the city a scene of desolation. Their joy at their return and their gratitude to the gods for deliverance from the barbarian invasion were expressed in an eager desire to rebuild the city more glorious than ever and to consecrate new and more magnificent temples to the gods. The rulers encouraged the ardent patriotism and religious fervor of the people, and at the same time strove to increase the influence of Athens in affairs common to all the Greeks. The prestige of the city was already great because of the bravery of the Athenians in the Persian wars, and this prestige was increased by the sagacity of the Athenian leaders Themistocles, Cimon, and Pericles. The last-named attained a position of ruling influence in the affairs of Athens about 460 B. C., and the next thirty years, the "era of Pericles," marked the period of the highest development of Greek art and architecture.

The funds contributed by the Greeks for the common defense were in the control of the Athenians and were removed through the influence of Pericles from Delos to Athens. He had little difficulty in convincing his fellow-citizens that the Athenians were not answerable to their allies for the disposition of these funds so long as protection from foreign invaders was assured. An enormous revenue was thus at the disposal of the Athenian Government, and after providing and storing in the city a sufficient supply of all things necessary for war, the remainder was largely used in beautifying the city with public and sacred buildings.

As the victor in the contest with Poseidon, Athene had a peculiar interest and claim on the Athenians. The country was hers by the verdict of the gods on Olympus. Then the revenue, without which there could be no government, no country, was especially hers, and the national treasury was in a peculiar sense the possession of the goddess—her temple. As such it was worthy of the most lavish expenditure and the highest effort. The temper of the people was shown when Phidias was discussing the material for the statue of Athene to be placed in the Parthenon. He had suggested the use of marble as the most durable, and the Athenians listened in silence; but when he added that it was cheap they bade him hold his peace. The most expensive material possible was demanded, and the statue was made of ivory and gold.

To the Greeks there could be no good without beauty, and what was beautiful needed no other attribute to recommend it. Their devotion to beauty was the one characteristic to which all others were subordinated, and to render to their own

particular goddess a temple that was less than the embodiment of beauty have been to them the grossest sacrilege.

Phidias, the friend and favorite of Pericles, was made "surveyor-genera had supervision of all the public improvements inaugurated by Pericles. and Callicrates were the architects of the Parthenon, but the decoratio more or less designed by Phidias himself, and perhaps executed by his ow though the extent of the scheme made the employment of other artists ne for the less essential parts.

An older temple which stood on the Acropolis had been burned by the P during their occupancy of the city, and the foundations remaining were ex and utilized for the Parthenon. Carefully selected white marble from Pentelicus was used throughout, in the construction of the buildings pr well as for the sculptured figures.

The base of the structure was a marble platform, or stylobate, reached b steps on all sides. The stylobate was 100 by 225 Attic feet, an Attic foo about a hundredth longer than ours. Around its edge rose the architectur ports of the roof, 46 Doric columns about 35 feet high, 17 appearing on ea and 8 on each end. Inside this outer peristyle there were at each end 6 columns surmounted by a frieze which extended all round the cella or the the temple. In the external entablature on all four sides were metope mented with sculptures in high relief, between Doric triglyphs or raised chamfered on the sides and deeply channeled with two vertical grooves. T was low pitched, and in the triangular spaces at the ends, called the pedi were the sculptured groups, which were the most striking external feature Parthenon.

THE STATUE OF ATHENE PARTHENOS.

But it was in the interior that stood the greatest artistic glory of Athe statue of Athene Parthenos. On it was lavished a wealth of gold and iv skillfully wrought that all thought of the value of the material was lost templation of the beauty of the workmanship and the sublimity of the artis ception. The statue itself was 33 feet high, and stood on a basis which rai crest of the helmet to 40 feet. Many writers of antiquity refer to it at gre less length, and Pausanias thus describes it:

> This work of art is in ivory and gold. In the middle of her helmet is an of the Sphinx * * * and on each side of the helmet are griffins w These griffins, says Aristus the Proconnesian in his poems, fought wi Arimaspians beyond the Issedones for the gold of the soil which the guarded. And the Arimaspians were all one-eyed men from their birth, a griffins were beasts like lions, with wings and mouths like eagles. But the of Athene is full length, with a tunic reaching to her feet, and on her breas head of Medusa worked in ivory, and in one hand she has a Victory 4 cubit in the other a spear, and at her feet a shield, and near the spear a dragon, is perhaps Erichthonius. And on the base of the statue is a representation birth of Pandora, the first woman according to Hesiod and other poets, for her there was no race of women.

Pliny tells us also that "on her shield he (Phidias) wrought in relief the of the Amazons on the swelling circuit (i. e. the convex surface), on the c part of the same target (buckler) the combats of gods and giants, while sandals [he wrought] those of the Lapithæ and Centaurs, so completely make every spot (literally, all divisions) available for art."[1]

In one of the dialogues ascribed to Plato[2] it is said that the nude parts v ivory, the eyes partly of ivory and partly of stone, and the dress and wea gold.

The robe was easily removable, having been made so at the instance of P

[1] Pliny, N. H., XXXVI, 18. The translation here given is by Prof. B. L. Gildersleeve, o Hopkins University.

[2] Hippias Major.

and contained gold valued at forty talents, or about $470,000. Pericles suggested taking this gold for the purposes of the war when the Athenians were hard pressed by the Spartans,[1] but the suggestion was made, evidently, to allay the fears of the people by recounting the wealth at their command, rather than with any real intention of allowing it to be used. The removability of the golden robe served an unexpected purpose, according to Plutarch, when the enemies of Pericles sought to injure him by charging that his favorite, Phidias, had stolen some of the gold supposed to have been put in the statue. Pericles at once silenced the accusers by bidding them to take it off and weigh it. Nevertheless, Phidias was imprisoned later on a charge of sacrilege, it being alleged that he introduced his own portrait and that of Pericles among the figures in the reliefs on the shield of Athene.[2]

THE PARTHENON FRIEZE.

The frieze around the cella was 520 Attic feet long, and was ornamented with a great number of figures, presumably representing the Panathenaic procession. This procession was a feature of the festival held every four years in honor of Athene, the occasion being the presentation of a new peplos to the divinity. The figures of the frieze were cut in low relief and were cunningly contrived to avoid the disadvantages of their peculiar position in which all the light that reached them came from below. Great variety was introduced in the composition; there were youthful horsemen, some preparing for the start and others in motion, Athenian cavalrymen in full gallop, charioteers, warriors in armor, musicians, youths with jars and dishes, men leading sacrificial animals, maidens, marshals, magistrates, priests, and, lastly, two groups of divinities. Every degree of motion appears, from the calmly conversing magistrates to the rushing charioteers and horsemen, but so skillfully are the parts of the procession blended that at no point is there any lack of harmony. Another peculiarity of the frieze is that all the heads are on substantially the same line, notwithstanding the differences in posture and movement; but here again the skill of the artist in the arrangement of the figures avoids all appearance of monotony.

THE METOPES.

There were originally 92 of the metopes. Their height was uniform, about 4.4 feet; but their width varied considerably, the average being slightly over 4 feet. They show great differences in style and technique, and were not only the work of many different hands, but they seem to belong to different periods of art development. The supposition regarding them is that they were the first of the Parthenon sculptures to be completed, and that they actually mark the development of art during the building of the Parthenon. It is well known that in the time of Phidias, and under his influence, Grecian sculpture was finally released from the restraints of archaic stiffness and rose to the heights of freedom, beauty, and sublimity. And the Parthenon metopes are supposed to mark that transition.

The full meaning of these sculptures is not satisfactorily explained, and none of the suggestions concerning them has included a reasonable central idea which might run through them all and connect them in a single related series. It is conceded, however, that those on the southern side of the building represented the battles between the Centaurs and Lapiths. The Lapiths were, according to the legend, the ancestors of the Greeks, and Peirithous was their chief. When he married Hippodamia he invited the Centaurs to the wedding feast, and while it was in progress Eurytus, a drunken Centaur, carried off the bride and caused the fights commemorated in the metopes.

---

[1] Thucydides, II, 13.

[2] Plutarch's life of Pericles.

The combats between the gods and the giants are supposed to have been sented in the eastern metopes, and the battles of the Amazons are belie many to have been the subject of those on the northern side. There is no factory clue to the meaning of those on the west.

THE EASTERN PEDIMENT.

The only reference in ancient literature to the groups of the pediments sentence from Pausanias: "And as regards the temple which they call th thenon, as you enter it everything portrayed on the gables relates to the b Athene, and behind is depicted the contest between Poseidon and Athene soil of Attica."[1] With this as a basis, endless speculations have arisen as significance of the different figures.

But little remains on which to base a judgment of the meaning of the group, but it is believed that the moment after the birth of the goddess wa for the representation and that the center of the pediment was occupied by Hephæstus, and the newly born Athene, and that the figures on the side of the minor deities. In one corner the sun god, Helios, is rising from t driving his famous horses, whose heads have just emerged from the water. to them is the superb nude figure of a man, commonly called Theseus, recli an easy attitude upon the skin of an animal. There follow two female f often referred to as Demeter and Persephone. They are seated, the arm resting familiarly upon the shoulder of the other. The next is the draped of a female, and is thought to be Iris, the messenger of the gods desc through the air to bear tidings of the wonderful event which has just taken

In the opposite angle Selene, the moon goddess, seems to be disappearin her horses into the ocean, and this, taken in connection with the appro Helios from the other side, is understood to symbolize the dawn of a new Attica upon the miraculous birth of her patron goddess. Near Selene ar female figures, two seated and the third reclining at full length with h resting upon the lap of the one in the center. These three are conceded to finest existing representations of the draped female figure, the drapery con nothing of the beauty of the superb forms beneath, but rather accentuati charm by its own gracefulness and freedom. The arms and heads of all t the figures are gone and we can form but an imperfect idea of their action. torsos other than those mentioned are preserved, one being that of a man st erect and the other of a draped female, evidently striding forward.

Nothing remains of the central, the most important personages of the what became of them, or when, is not known.

THE WESTERN PEDIMENT.

Of the western pediment even less remains than of the eastern. The shoulders, and back of Poseidon, the torso of a reclining river god, a h female figure leaning against a badly mutilated representation of a god, a a crouching male figure, another male torso, fragments of horses, and a fe cellaneous scraps, are all that is left of this series of statues. Fortunately ever, we know from extant drawings the position and attitude of nearly figures.

The story is that both Athene and Poseidon sought the possession of and it was agreed that the honor should fall to the one who produced th useful gift. Poseidon struck the rock with his trident and a salt spring forth. At the command of Athene an olive tree sprang up, and she imme received the award. The sculptor, according to the general acceptation, sents this contest before the assemblage of gods on Mount Olympus.

[1] Pausanias I, 2'.

The principal figures were those of Athene and Poseidon in the center, and as both seem to be preparing to leave the scene, the moment chosen for representation was evidently that immediately after the decision.

The head of Athene and the arms of both figures were missing when the drawings were made, and the action is therefore uncertain; but Athene seems to go in triumph to her chariot while Poseidon, full of anger, retreats toward his. Both chariots are awaiting their occupants, that of Athene being hitched to two rearing steeds and that of Poseidon being drawn by hippocamps, or monsters with horses' bodies and fishes' tails.

There were originally eight or nine attendant deities on each side, those on the side of Athene being usually recognized as Nike, the charioteer of the goddess; Hermes, who stands in the background behind the horses; Persephone and Demeter, seated with the boy Iacchus between them striving to get away from the scene of excitement; then Hebe and Heracles, and finally, in the angle, the river god Cephissus, who has been unexpectedly aroused and raises himself on his arm to look languidly toward the center.

On the side of Poseidon is a figure supposed to be Amphitrite, seated in her husband's chariot; next an indistinguishable figure in the background; Leucothea, with a child; then the nude Aphrodite seated on the knee of Thalassa, and attended by Eros; next is a nereid and the god Illissus, with the nymph Calirrhoe in the angle.

It is noticed that the figures in the angles are apparently oblivious to the drama enacted in the center, or take but little interest in it, while the action increases in intensity the nearer we approach to the main actors, and in them every muscle is tense with earnestness and excitement.

THE USE OF COLOR AND OF METAL.

Color was freely used in Doric temples, and the Parthenon and its decorations were no exceptions to the rule. Metal ornaments and accessories were used in connection with the statues, and many necessary parts not shown in the reliefs, especially of the frieze, were undoubtedly supplied with the brush. Athene Parthenos herself was adorned by the painter's art, and her golden robe is believed to have been toned down and shaded so as not to contrast too rudely with the nude parts.

The external architrave was probably left bare originally, but in later years shields and a metal inscription were placed upon it. The shields were probably those Alexander the Great sent to the Athenians after his defeat of the Persians at Granicus; and an American student, Mr. Eugene P. Andrews, recently distinguished himself by deciphering the inscription, which was of the time of Nero, by means of the position of the holes into which nails had been driven to fasten on the metal letters.[1]

ARCHITECTURAL REFINEMENTS.

In its architectural features there was much in the Parthenon that was not apparent to the casual observer, and much that escaped the attention of modern students until a comparatively recent date. The precision and beauty of the workmanship in even the minutest details and the excellence of the materials have long been observed. But unexpected refinements of architecture have been discovered from time to time, and the belief is justified that even now all the beauties have not been revealed. It was for a long time assumed, quite naturally, that the sides of the columns were straight lines, but since 1810 investigations have shown that they are bounded by delicate hyperbolic curves, not perceptible without close scrutiny, but which have been determined to amount to $\frac{1}{100}$ of the height of the columns.

[1] See Century Magazine for June, 1897, for Mr. Andrews's account of his feat.

The architrave, too, is curved to form a very flat arch, and the stylobate, larly, is curved upward. The pillars are not vertical, but incline towar center nearly a quarter of a foot, and the spaces between them are irregula nearly every instance the curves, where curves are apparent, were not a circles, but were conic sections, either hyperbolas or parabolas.

All these niceties evidently resulted from a keen appreciation of the effe optical illusion, but the precise reasons for some of them have not yet bee covered. Though the laws which governed these details be unknown to u nevertheless feel the effect of their absence in the stiffness and formality of ings erected in imitation of Greek temples, but without their subtle refinen It is likely that in much that they did, the designers were guided solely highly developed artistic instinct, and could not themselves have assig reason. The same acute perception of the requirements of special condition the same delicate ingenuity in meeting them, that prevailed throughout th struction of the Parthenon, are illustrated in the story of the statue of A which Phidias is said to have made in competition with Alcamenes. Wh rival statues were exhibited on the ground, that of Alcamenes was decidedl ferred by the Athenian public, but when they were elevated upon the hig umns for which they were intended, the work of Phidias was so plainly su to the other that Alcamenes became the laughing stock.

LATER HISTORY OF THE PARTHENON.

The Parthenon passed unscathed through the varied fortunes of the civil which distracted Greece, and retained its character as a sacred treasure until after the death of Alexander the Great in 323 B. C. In the dissension wars that followed that event Athens was a conspicuous sufferer. Her d erate citizens were the prey of first one conqueror and then another, and treated them all with servile adulation. Demetrius Poliorcetes was quarter the Athenians in the Parthenon itself, and the sacred temple became the of wild debauchery and licentiousness. He despoiled it of its treasure exce only the vessels and other articles distinctly sacred, but Lachares, who g the ascendency in the city when Demetrius had fled, well nigh complete work of spoliation. He thought only of enriching himself, and nothing w sacred for his rapacity. Pausanias states that he removed the shields fro temple, and even robbed the goddess of her golden robe. But he was oblig flee the city suddenly and was not able to take away his plunder; so Atl robe was restored and the statue was intact several centuries later at the ti the visit of Pausanias, which occurred about 170 A. D.

After the treasure had been removed the Parthenon lost much of its import but still remained the central point of the Panathenaic festival and the pla the distribution of the prizes for the contests. With the decline of that fe the prestige of the Parthenon was gone.

What finally became of Athene Parthenos is not definitely known. A remained under Macedonian influence from the time of Alexander to the con of Greece by the Romans in 146 B. C. Under the latter the city enjoyed perity; its temples not only remained undisturbed, but others were erecte great pains were taken to restore the city to its former splendor. It was after the spread of Christianity that the statue disappeared. After remaini all its glory for nine hundred years "with all the freshness of a modern wor all the beauty of an ancient one," it was removed from its place about the m of the fifth century. After that nothing remains to tell us of its fate. The rel of those Greeks who refused to accept the teachings of Christ in time degene into mere idol worship, and when Christianity gained the ascendency the athy for the pagan gods was in inverse ratio to the reverence in which the

formerly been held. The work of Phidias had especially invited adoration from its wonderful beauty and perfection, and it is natural to suppose that it was among the first to suffer when the Christians "threw down the false gods."

The Parthenon became a Christian church in the fifth century, and thereafter its character was changed according to the religions of the successive conquerors of Athens. Its first dedication as a Christian church was to St. Sophia, but later it was called the Church of the Mother of God, and retained that name as long as it was held by Christians. Many alterations were made in it from time to time to adapt it to its new uses, the principal of them being the construction of an apse at the eastern end of the building. This necessitated the removal of some of the slabs of the frieze, but they were carefully preserved and placed in a safe position inside. After the fall of Constantinople and the conquest of the Byzantine Empire by the Turks, the Parthenon once more changed its religion and this time became a Mohammedan mosque. Again minor changes were made to suit the caprices of the new occupants, and among them the Pentelic marble of the interior was white-washed! On the top was erected a slender minaret, from which the muezzin daily cried the Mohammedan call to prayer.

For over two hundred years after the fall of the Byzantine Empire Athens was seldom heard of by Christian Europe, and during the entire period of Turkish domination but two events occurred to entitle the city to a place in the annals of Christian nations. The Venetians attempted unsuccessfully to capture the city in 1464, and a similar and more successful effort was made by them in 1687. An army under Francesco Morosini had been sent by the Venetian senate into Greece after the defeat of the Turks by John Sobieski at Vienna, and had gained a number of important victories in Morea. Morosini, in September, 1687, sent a force, composed largely of mercenaries, under Königsmark, a Swede, to reduce Athens. He occupied the city, but the Turks remained in the Acropolis, which they strongly fortified. Königsmark planted his artillery advantageously, began the bombardment of the citadel, and soon had effected the ruin of the beautiful structures on its summit which had passed through the vicissitudes of two thousand years with undiminished glory. The Propylæa bore the brunt of the heaviest cannonading, the temple of Nike Apteros was entirely destroyed, and a bursting shell caused the explosion of a powder magazine in the Parthenon and completed the ruin which the steady artillery fire had begun. The explosion wrecked the center of the building irretrievably, but the pediments were only slightly injured. When he had gained possession of the Acropolis, Morosini, thinking to add to the glory of his campaign by sending home such choice art treasures, sought to remove the central group of figures from the western pediment; but his soldiers were more accustomed to handling artillery than statuary, and allowed the precious sculptures to fall, shattering them in a thousand pieces.

The Venetians held Athens but a short time, and when the Turks returned they saw in the mass of débris on the Acropolis only a source from which they might obtain building material, or a quarry from which they might get stones to burn into lime. The Parthenon bore no longer the semblance of a building which could serve as a mosque, the highest use which their civilization suggested; and so far as any appreciation of its sculptures was concerned, that was not to be expected from Musselmans, whose Koran forbids the fashioning of the likeness of any living thing. There was no motive left, therefore, to prevent the complete devastation of the remains of the Parthenon by the Turks of that period, so far as it suited their convenience and interest, and for the next hundred years and more there was a gradual disappearance of such sculptures as were left after that fatal bombardment of 1687.

From time to time, before and after that event, drawings had been made by visitors to Athens of different parts of the Parthenon, and it is to them that we are indebted for nearly all our knowledge of some of its features. The most impor-

tant of these drawings were made by Jacques Carrey, a French painter, who was employed by Marquis de Nointel, the French ambassador at Constantinople, in 1674. The structure was substantially intact at that time, and though but two weeks were granted him, the artist succeeded in drawing both the pediment groups, thirty-two of the metopes, and about three-fourths of the frieze. These drawings, twenty-one in number, are still preserved in the Bibliothèque Nationale in Paris.

The eastern pediment had lost its principal figures long before the time of Carrey, but when or by whom they were removed there is no evidence to show.

Turkish limekilns were not the only foes that wrought mischief to the Parthenon sculptures during the period of Turkish rule, for the relic hunter was as active then as he is now, and he had no difficulty in securing permission from the corrupt officials to remove legs, arms, or other parts of statues.

The French ambassador, Count Choiseul-Gouffier, and Fauvel, an artist in his employ, in 1797, removed entire a slab of the frieze and one of the metopes and sent them to France. Prompted by this, perhaps, the British ambassador, the Earl of Elgin, secured permission from the Turkish Government, a few years later, for his artists to make drawings and plaster casts and to take away pieces of stone with inscriptions. By suitable "presents" he induced the Turkish mayor at Athens to so construe this as to allow him to take away anything he chose. He employed 300 or 400 men a day in the work of removal. Everything bearing the slightest resemblance to a sculptured figure and every fragment that seemed to possess any value whatever was taken, whether it was found on the ground or still in its place on the building.[1]

The difficulties and annoyances encountered were many and great and the expense was enormous, but the British Government finally repaid Lord Elgin about $175,000 of his expenditure and the statuary was lodged in the British Museum, where it still remains under the name of the "Elgin Marbles."

Little remains now of the Parthenon on its own stylobate but the badly damaged columns at the ends and shattered portions of the entablature and pediments.

Such is the history of architecture's finest example. It has been described, studied, measured, discussed in all its details, enthusiastically and lovingly, through centuries ancient and modern. Learned conjecture has been brought to bear upon its lost features, and unmeasured admiration is ever expressed for what remains. Restorations and reproductions in great number have been made or suggested and models are to be found in every art gallery. At least one noteworthy attempt has been made to reproduce the color scheme, that of Chipiez, the French archæologist, who made the famous 12-foot model for the Metropolitan Museum in New York; but it remained for the Tennessee Centennial to be the first to build a full-sized model with colors, restorations of the sculptured ornaments, and all in approximate exactness of detail.

The Tennessee Parthenon.

It is not to be supposed that any claim was made of strict accuracy or that the structure was more than "a model," as its architect called it. The cella was built of brick, covered with "staff," the columns were of framework similarly treated, and the floor and stylobate were of wood. The structure was intended for temporary uses only, and necessarily cost was considered in all things. It was to save expense that the frieze was omitted, and a like consideration led to the use of the same group in both the pediments, and to the reproduction of only a few

[1] The figures called "Hebe" and "Heracles," in a badly decayed condition, and the lower part of "Calirrhoe" are still on the western pediment, and the horses' heads, in low relief, remain on the tympanum of the eastern. Several of the metopes also remain, but are so defaced as to be indistinguishable.

(thirty-three) metopes, which were repeated all round the building. This must be taken as an evidence of wisdom as well as economy. For if any attempt had been made to supply the missing figures in the eastern pediment or to design metopes to take the place of those that are lost or defaced the result would have been disastrous, for the work naturally would not have been the work of a Phidias. But Carrey's drawings made it possible to learn enough of the western group to reproduce it without jarring faults, and enough metopes still exist in fair preservation for their reproduction to give the entablature a satisfactory Phidian air if one were not so critical as to object to the repetition, which was not painfully conspicuous.

The General Educational Exhibit.

The scheme of classification of the Paris Exposition of 1900 gives the place of honor to education, and it is stated in the advance notices that especial attention will be given to the educational exhibits. These great expositions serve as models for the smaller ones that are held for years afterwards, and it is likely that the next century will see better treatment of education than it has had in the past. There has been no disposition to slight the claims of the educational material, for the authorities of the past expositions have been as liberal as it seemed to them wise to be. Nevertheless, agriculture, machinery, electricity, manufactures, and the fine arts have had precedence, and education has received what was left after the demands of these classes were satisfied. It is a matter of relative values, and the announcements from Paris indicate a new relative value to be placed on education. It is not to be valued as fourth or fifth in importance, but as first; and exhibitors of this class will have cause for rejoicing.

At Nashville there were educational displays in the Education and Hygiene building, the two galleries of the Commerce building, which were not connected, the Children's building, and the Negro building; and, lastly, the exhibit of the Bureau of Education, which had no connection with others of the same class, was in the Government building.

The galleries of Commerce were reached only by long flights of stairs, and the exhibits in them were greatly handicapped by their inaccessibility.

In the Children's building the ground floor was used as an audience hall, a kindergarten room, and for the display of curios. A great deal of kindergarten work was hung on the walls of the audience room. The floor above was occupied by some of the exhibits of elementary schools, and for the purpose it suffered from the same difficulty as the Commerce galleries, for visitors show an invincible objection to climbing stairs.

In the Education and Hygiene building the exhibits fared better. Nearly all the institutions of higher grade had their exhibits there, and being on the ground floor they had their just proportion of visitors. The same was true of the institutions for the colored race, whose displays were in the Negro building.

In mentioning individual exhibits, I would refer first to those of the University of Tennessee, Vanderbilt University, and the city schools of Nashville. All these were admirable in both the matter and the manner of display. The last-named exhibit was one of those that were in the Commerce building, but the other two were advantageously placed in the Education and Hygiene building. The University of Tennessee people are experienced exhibitors, and state that they have had excellent results from their work in this line. The exhibit was attended by a man who was selected for his special fitness in setting forth the facilities and advantages of the institution in a tactful and effective way.

The Peabody Normal School had a very creditable display; and several other institutions had their spaces attractively and tastefully furnished, apparently as resting places, where visitors might look at portraits of distinguished alumni or at albums of photographic views.

In the Negro building educational institutions were predominant, and th trial side of their work was most prominently shown. Among the most co ous exhibits were those of Fisk University, Lincoln University, Tuskege Normal and Industrial School, and the Industrial and Normal School mal, Ala.

The most successful feature of the educational department was the kinde conducted daily in the children's building. The teachers were fully aliv spirit of their work, and the kindergarten was a revelation to hundreds o in a section of the country where such methods of instruction are unfort too little known. Whether regarded as an exhibit pure and simple or a tional missionary work in a suitable field, the kindergarten was in eve admirable. It was in charge of a young lady who received her training public kindergartens of St. Louis.

No attempt was made to hold conventions and congresses under the aus the Exposition. A number of meetings were held in the Auditorium, Exposition authorities had little or no connection with them further tha nish the place of meeting. Those attending paid for their admission grounds as all other visitors did. The meetings were encouraged, of cou source of revenue, but their success or failure was not in any sense charg the Exposition itself.

The exercises on "Public School Art Day," May 7, were the nearest appr an educational convention that took place. Addresses were made by Dr Harris, United States Commissioner of Education; Miss Josephine C. Locke visor of drawing in the Chicago public schools; F. Hopkinson Smith, the and artist, and others.

THE EXHIBIT OF THE BUREAU OF EDUCATION.

Since statistics and educational information are the special province Bureau, the first thought and the most time were given to the prepar statistical charts. They are not the best exposition material, but they a representative of the Bureau's principal function. A large chart was m wall display which showed the progress of education in the South for twen past. The public school system in the Southern States has had its greatest in that time and the figures of the chart brought out the remarkable stri have been made. Eighty charts were prepared and displayed in "wing f about half of which were devoted to the statistics of education in the States and half to education in foreign countries. There were among these charts that were comparative in character, and showed for several count relative number of male and of female teachers, the relative number of elen pupils, relative illiteracy, etc.

Allied to the charts in general character were eight large maps of the States, upon which were shown the location of the higher educational insti the distribution of public school and high school attendance, and of publi ries, and the percentage of illiteracy in the several States of the Union. maps were very valuable, and were constantly examined by interested visi

Twelve cases of photographs were shown in which were views of typical tional institutions classified as follows: Public schools, normal schools, sem for girls, academies for boys, institutions for the colored race, colleges for universities and colleges, agricultural and mechanical colleges, institutes nology, and schools of medicine. In each case the institutions represent selected to cover as wide a field as possible, and there were pictures fro State in the Union. Comparatively few photographs were included from ville and the vicinity, on the supposition that the schools in the neigh would all have exhibits of their own, and that Tennessee material in ou

would be of little interest. This proved to be an error. The few Tennessee photographs in the collection were more popular than all the rest together, and a great many visitors expressed disappointment at not seeing more of their home institutions represented. People in looking through the cases would almost invariably hunt for scenes with which they were familiar. I am led to believe, therefore, that a liberal display of the pictures of local institutions would add to the interest of such a collection, and by inducing people to "proceed from the known to the unknown" would make the whole of greater use and value.

A number of water-color pictures were made to indicate the progress of school architecture. They showed respectively a primitive log-cabin schoolhouse, an interior of the same, a "dugout" school of the Western plains, the "little red schoolhouse" so familiar in educational literature, a city school building of thirty years ago, and lastly a typical modern building. These pictures, with the exception of the last named, were made, and well made, by Mr. Spencer B. Nicholls, a young artist of this city. Mr. Edward W. Donn, of the firm of Donn & Peter, architects, originated the design and drew the picture of the present day structure. The most apparent and conspicuous improvement that relates to schools has been in the matter of equipment. Comparatively few years have elapsed since the prevailing type of schoolhouse in this country was of very primitive character. The rural aspect of the country as a whole and the undeveloped condition of the school system operated to associate the school in the popular mind most intimately with the log cabin or the simple one-room frame structure. It is unnecessary to say that this is no longer true. Typical American life of to-day is life in cities and villages, and the representative schoolhouse is the commodious 8-room building so frequently seen the country over. This evolution was very well shown by the pictures exhibited, and they attracted wide attention.

The twenty historical pictures of school punishments which were made for the Bureau exhibit at the Atlanta Exposition by Mr. Felix E. Mahony were again displayed, and were again an attractive and popular feature.

That part of the exhibit which related to Alaska was during a considerable part of the summer one of the most sought-for exhibits on the grounds. The excitement caused by the discovery of gold on the Yukon River was attended by a widespread desire to learn as much as possible of that little-known territory, and made everything connected with Alaska an object of interest. The Bureau's exhibit was prepared before the gold discoveries were made, and for that reason had but little to show from the vicinity of the "diggings." But at my request Mr. William Hamilton, the assistant general agent of education, kindly indicated on a map the points around which the most of interest is centered, and wrote a letter describing the region, the mode of reaching it, etc. Both the map and the letter were framed and hung in a conspicuous place, and were nearly always surrounded by eager visitors, since that information was not then readily accessible elsewhere.

Nearly all the material in the Alaska exhibit was furnished by Dr. Sheldon Jackson, the general agent of education, and by Mr. Hamilton. It comprised two show cases filled with curios, eighty sheets of statistics, photographs, drawings, etc., showing as far as possible the conditions of education in the Territory, and a collection of water-color paintings of Alaskan wild flowers made by Miss E. Leslie Jackson. The curios included totem poles, models of fur garments, specimens of carving, weaving, and needlework, and the like. The native drawings were remarkable for the conception of perspective they displayed, and for an accuracy of execution that was surprising in those whose instruction had been of the most limited and the rudest sort. But few of the "artists" had attended the Government schools at all.

The flower pictures of Miss Jackson were noteworthy for their artistic excellence as well as for their botanical correctness, and were much admired. To most

visitors the most surprising part of it was that there were such flowers in A at all, and the exhibit did much to dispel the prevalent idea that Alaska is of perpetual snow and ice.

In the matter of installation the changes introduced were more in the nat improvements over old ideas than of radical innovations. The photogra typical educational institutions were mounted on heavy cards and hung in l frames in neat cabinets. Since wall space was limited, these cabinets were structed upon tables, six upon each, and the result was two very handsome of furniture.

Between the space assigned to this Bureau and that of the Indian Offi screens were erected, one on each side, with a sufficient space for passage be The screens were 10 feet long and 8 feet high, and were substantial and mental. The frames were of polished oak, to correspond with the rest of t niture, and the central portions were covered with burlap similar to th covering. They served excellently for additional hanging space for picture

Wing frames, hung in rows above 8-foot tables, were used for the stat charts and for the Alaska photographs; and the maps showing distribut educational institutions were hung upon self-acting rollers, in wall cases s structed as to permit the ready examination of any map in either case.

The show cases used for the Alaska curios were like those commonly s stores, save that they were of glass on all sides. The frames were perfectly though of highly polished oak. The handsome appearance of the furnitu the great number of pictures on the walls made attempts at ornamentation own sake unnecessary. Four groups of Rogers' statuettes of school subjec a large brass telescope were, however, used to good advantage on the tops cases.

I have appended a catalogue of the exhibits in the Government building matter worthy of wider and more careful attention than they could receive exhibit, a number of the statistical charts mentioned in the foregoing parag

I am, sir, very respectfully,

J. C. BOYKIN, *Special A*

Hon. W. T. HARRIS,
Commissioner of Education.

DESCRIPTION OF THE UNITED STATES GOVERNMENT EXHIBIT.[1]

The Congress of the United States, by act approved December 22, 1896, pr for a representation at the Tennessee Centennial Exposition by the Governm the United States from its executive departments, the Smithsonian Insti and Fish Commission of "such articles and materials as illustrate the fu and administrative faculty of the Government in time of peace and its res as a war power, tending to demonstrate the nature of our institutions an adaptation to the wants of the people." To secure a complete and harm arrangement of the exhibit, the act provided for a board of management composed of a representative designated by the head of each department following representatives were respectively appointed: E. I. Renick, Depa of State; C. E. Kemper, Treasury Department; Capt. H. C. Ward, U. S. A Department; Lieut. C. M. McCormick, U. S. N., Navy Department; J. B. F low, Post-Office Department; F. W. Clarke, Department of the Interior; Strong, Department of Justice; C. W. Dabney, jr., Department of Agric F. W. True, Smithsonian Institution and United States National Museu de C. Ravenel, United States Fish Commission.

Dr. Charles W. Dabney, jr., president of the University of Tennessee and ant Secretary of Agriculture, was appointed by President Cleveland as cha of the board. The organization was completed by the selection of W. V. C the National Museum, as secretary, and H. P. R. Holt, of the Treasury D ment, as disbursing officer.

[1] Based upon the description prepared by the representatives of the several departme presented to the president of the Exposition by Mr. W. V. Cox, secretary of the Gove board of management, on the day of opening.

THE EXECUTIVE MANSION.

This exhibit is small and for convenience is made part of the exhibit of the Department of State. It contains a portrait of the President and Vice-President, steel engravings of all the Presidents of the United States conveniently arranged, and a photograph of the Executive Mansion. The official working of the President's office is shown by a blank form of nomination to the Senate, commissions issued for different offices, samples of stationery, the official seal, a warrant directing the Secretary of State to place the seal of the United States upon an executive instrument, and forms of letters used.

THE DEPARTMENT OF STATE.

The historical archives of this Department contain many rare collections of papers and letters written by men connected with the foundation of the Government. There is on exhibition one volume of the Washington Papers containing manuscript letters of George Washington, including that of December 29, 1783, resigning his commission as General of the Army. This collection comprises 313 volumes. There is one volume from each of the following collections: The Madison Papers, in 75 volumes; the Jefferson Papers, in 131 volumes; the Hamilton Papers, in 65 volumes; the Monroe Papers, in 22 volumes, and the Franklin Papers, in 34 volumes. These valuable documents have all been purchased by the Government. All of them have been carefully restored, mounted on sheets, indexed, and bound in volumes, except the Washington and Hamilton Papers, and the work on these is progressing. The Department has in its custody the original Declaration of Independence, but this precious document is so faded that it is necessary to protect it from the light. A facsimile is exhibited, with 38 portraits of the signers. Accompanying these is an artotype copy of the original rough draft, containing the interlineations and corrections by Adams and Franklin. An artotype reproduction of the original Constitution of the United States, with 36 portraits of the signers, makes an interesting exhibit. These artotype reproductions are so like the originals that they are considered equally good for exhibition.

There is a fine collection of autograph letters from foreign officials and celebrities to the President of the United States, among them being Robespierre, Barere, Carnot, Louis, King of France, Napoleon I, Jerome Bonaparte, Queen Victoria, Alexander I, of Russia; William I, Emperor of Germany; President Diaz, of Mexico; Ranavalmonicao, Queen of Madagascar; Chulalongkorn, King of Siam. The autographs of the Presidents are shown in original proclamations on various subjects, the only signature lacking being that of President William Henry Harrison, who died before signing a proclamation. There is a set of portraits of the Secretaries of State; maps showing the growth of the United States diplomatic and consular service; maps showing the expansion of the territory of the United States under treaty provisions; Andrew Jackson's sword; swords presented to the United States by Japan and Siam; Malay krises captured from pirates; a large gold medal set with diamonds, containing a fine cameo with a representation of Columbus discovering America, designed and presented to the President of the United States by the Sultan of Turkey in commemoration of the four hundredth anniversary of the discovery of America; a statuette of George Washington by Baron Marchetti from the original study and model by his master, Houdon, of Paris, in 1785–1790, for an equestrian statue, which, according to Thomas Jefferson, then United States minister to France, was sent to America by Houdon with the expectation of receiving an order from the Congress of the United States to have it cast in bronze, but the model was destroyed by fire in Washington, leaving this statuette as the only survival. It was in the possession of the Duke of York, and at the time of the Chicago Exposition he presented it to the United States and it was placed in the custody of this Department.

The workings of the various bureaus of the Department are carefully outlined, particularly in the passport division, which is of great interest to those contemplating a trip abroad. It shows the forms of passports used by the Department, the forms of application for a passport, those to be used by a native citizen, by a naturalized citizen, and by persons claiming citizenship through the naturalization of their husband or parent; instructions governing the issuance of passports, and a pamphlet (for free distribution) showing the passport regulations of foreign countries.

THE TREASURY DEPARTMENT.

The administrative functions of the Treasury Department may be divided into three branches—the accounting, the financial, and the commercial. The first of these consists of examining and revising every expenditure of the Government,

and no money appropriated by Congress for the maintenance of the Genera ernment or any of its branches can be legally expended except upon the ap of the Secretary of the Treasury. This branch of the Department, being clerical, can not be illustrated by an exhibit.

The financial branch of the Department is illustrated by a complete set of currency issued by the Government, from a 10-cent shinplaster to a $10,000 gol The process of coining the money of the Government is shown by operating press, which has been in constant use in the Philadelphia Mint for fifty-two It has a capacity of $90,000 per hour, and in coining a silver dollar strikes equal to the weight of 100 tons. A medal specially prepared for the Exp will be coined during the period of the Centennial. In connection with th exhibit is also shown a complete set of the current coins of 70 of the pal nations of the world, and a full set of all the national medals authori Congress.

The Bureau of Engraving and Printing, in addition to showing all the money of the United States, will exhibit a plate printing press in operation trating the manner in which United States notes are printed, and upon will be printed a souvenir card of the Exposition, showing the White Hou Capitol at Washington and portraits of the President and Vice-President.

The commercial branch of the Department has control of all matters pe ing to the collection of revenue, and, by analogy, Congress has assigned Secretary of the Treasury the duty of enforcing all laws relating to domest foreign commerce of the United States, including the Light-House Establish the Life-Saving Service, the Marine-Hospital Service, the Coast and Ge Survey, and similar branches of Government business.

The Light-House Establishment exhibits a more complete assortment of apparatus and furnishings than ever before shown, consisting, in part, of on second-order bivalve lens, weighing over 8 tons, one third-order lens, flashi and white lights alternately, and one fourth-order lens, all of which are sh operation, together with all the lighting appliances in use by the Departm

The Marine-Hospital Service's exhibit will be illustrative of the functions Government in preventing the introduction and spread of epidemic diseases establishment of quarantine stations, where all vessels and passengers are ined by trained surgeons, and by the erection of Government hospitals f care and treatment of American and foreign seamen. The exhibit cons models and photographs of quarantine stations and hospitals, hospital furni and fittings, disinfecting apparatus and surgical instruments.

The Treasury Department, through the medium of the Coast and Geodeti vey, is the custodian of the standard weights and measures of the United S and, under the authority of Congress, supplies each State with a set of sta weights and measures, from which all others are made and tested, and thes be exhibited by the Survey, accompanied by models of the metric system.

The Supervising Architect of the Treasury has control of the design and tion of all public buildings, and the exhibit of his office consists of water photographs, and sketch plans of the most important buildings erected Government.

THE WAR DEPARTMENT.

The War Department exhibit represents four branches of the Army, vi Quartermaster's, Engineer's, Ordnance, and Signal Corps departments.

Quartermaster's Department.—This department exhibits lay figures, mo and dismounted, showing the uniforms of officers and men from 1776 to th ent date, and that of a Puritan soldier of 1620; also a case of chevrons, rep ing the various insignia of rank of the enlisted branch; two pack mules, sh old and new methods of packing used by troops on a campaign in the far against Indians, and where wagon transportation is not available or practi silken colors of regiments, battalions, army corps, divisions, and brigades, silken guidon of the Seventh Cavalry, of Custer fame.

Engineer's Department.—This department exhibits models of Harlem improvement, St. Marys Falls Canal lock, pontoon bridge apparatus, mort tery at Hell Gate, block house and lift-gun battery; a number of photogra series of sixteen transparencies, and a submarine-mine group, showing ho harbors and rivers are protected.

Ordnance Department.—This department displays a light-battery field gu carriage and limber complete; Gatling gun, with carriage and limber co field mortar and carriage; gun rack, with large collection of ancient and m guns and revolvers, including those now in use in the Army; samples of t ferent swords, sabers, and scabbards used in the Army; cavalry and infantry

complete equipments; armor-piercing shot for 8, 10, and 12 inch rifles; shells for 7-inch howitzer and 5-inch siege gun; sample boards of fuses and ammunition, both reloading and nonreloading.

Signal Corps.—This exhibit includes the various apparatus used for day and night signaling; photographs of arctic scenes; the famous relics of the Greely relief expedition—the medicine chest, the seal-skin boots boiled up to make their last meal, the improvised scales used to weigh rations, the hatchet and piece of flag carried by Lockwood and Brainerd to the farthest north, the oar with its distress signal, a sledge made from pieces of boards used by Rice and Frederick in an unsuccessful attempt to cross to Baird Inlet to obtain the beef which had been cached there. Rice died on this sledge during this trip and was buried in the snow.

THE NAVY DEPARTMENT.

The exhibit of the United States Navy Department is assembled especially to show the present status of the Navy. Nothing is exhibited on account of its historical value only. The few old articles exhibited are only intended to accentuate the modern implements of naval warfare. It is endeavored to give this exhibit the greatest intellectual value, and to do this prominence has been given to the Bureaus of Construction, Equipment, Ordnance, and Steam Engineering, while other bureaus have received little or no attention.

In the middle of the rotunda is a full-sized model of the military mast of the gunboat *Helena* (a miniature of this vessel being included in the fleet of models). This mast carries two military tops, in each of which are mounted two 1-pound rapid-firing guns. On the platform, between the tops, a 30,000-candlepower search light is mounted. The bronze ship's bell, mounted near the base of the mast, was made for the U. S. S. *Canandaigua*. Service and international signal flags are flown from the masthead.

Leaving the mast, the first exhibit in the Navy Department space is a full-sized model of a battle ship's anchor, weight 14,000 pounds, attached to which is a short section of 2¼-inch chain cable, with club link and shackle. At the crown of the anchor will be placed a model of the U. S. gunboat *Nashville*, made especially for this Exposition. This vessel heads the fleet of ship models, in which will be found one or more vessels of each of the various types of battle ships, monitors, cruisers, and gunboats, with a concise description of each. The lines of these models are made with extreme accuracy, and the models themselves show the perfection of the mechanic's art.

Following the ship models will be found a Howell and a Whitehead torpedo, and a main-deck torpedo gun, used in firing Whitehead torpedoes. Adjacent to the torpedo gun is a full-sized half-section model of a 13-inch rifle, showing, in the section, how the tubes, jacket, and hoops are locked. On line with the bore of the gun, and extending to the end of the allotted space, is a rough painting, illustrating the penetration of a 13-inch projectile fired with an initial velocity of 2,400 feet per second, at a target consisting of steel, wood, granite, and brick. Alongside this model are shells of all calibers, from 13 inches down, a number of which have been fired against armor and show more or less distortion. Model powder charges for 13-inch and 6-inch guns, with their cases, are here displayed. Attention is called to a sample of one of the return springs for the 13-inch gun, with its specifications. A breech block for a 10-inch gun is mounted near breech of 13-inch gun.

Following the line of the exhibit is found a 5-inch rapid-fire rifle, a Hotchkiss, and a Driggs-Schroeder 6-pounder, a Hotchkiss 1-pounder, a Hotchkiss revolving cannon, and a 3-inch field gun on its carriage, all with their ammunition and drill cartridges. A few pieces of old cannon, possessing historical value, serve to show the contrast and development of modern ordnance.

A nickel model of the Hichborn turret divides the heavier ordnance from machine guns and small arms. The latter consist of a Gatling gun and its successor, the Colt automatic gun, the latest and most approved adaptation of the Navy. This gun fires the same cartridges (caliber 6 millimeters, or about 0.236 inch) as the new Navy rifle, one of which is mounted on a tripod, from which sections of boiler plates, showing penetration and efficiency, are suspended. A case near by contains three of these rifles, which show sections, through the breech mechanism, at different positions of firing.

In front of this case is displayed a Franklin life buoy suspended from a section of a ship's side. Immediately in rear of this is shown a plaster development of the Caribbean Sea, and the engraved plate from which charts of this sea are printed, together with a portfolio of charts, illustrating the chart work of the Hydrographic Office. On the wall are displayed pilot, current, storm, and other charts.

Various instruments of navigation, samples of primers, fuses, pressure
and of the various powders used in the service, and other small articles ar
ited in a show case near by, and alongside this stands the latest type of c
sating binnacle compass complete.

Following these are seen a propeller blade of the U. S. S. *Maine*, a se
crank shaft of the same vessel, and a steam-launch engine and its propel
large drawing of the engines of the U. S. S. *New York* is suspended on the

In a wall case are shown samples of the various kinds of rope made in the
States rope-walk, at the Boston Navy-Yard.

A diving suit, with complete equipment of air pump, piping, telephor
stands prominently against the rear wall of this exhibit.

On the side wall will be found four cabinets containing a large number
tographs illustrating various subjects connected with the naval service
on board ship.

Attention is called to the drawing in the center of this wall, illustrat
relative strength of the different naval powers of the world. On each side
are numbers of paintings, drawings, engravings, and numerous large phot
illustrative of naval vessels and scenes, the painting of the *Nashville* havi
made especially for the Exposition.

Besides what is shown in the Government building, the Navy Departm
has a medical exhibit in the building of Hygiene and Education, which co
most of the hygienic implements used in the naval service, besides models
interest.

THE POST-OFFICE DEPARTMENT.

Stamp division.—The following collections are displayed: A series of
States postage stamps from their introduction in 1847, including Depa
special-delivery, postage-due, and newspaper and periodical stamps; also
stamped envelopes from 1853 to 1893, and sets of foreign stamps and post
to 1893 from all stamp-issuing countries of the world.

Equipment division.—This branch of the service is represented by mo
uniformed mail carriers of the United States and other countries, fully e
with the insignia of the service of their respective Governments; a figur
Indian mail carrier, with toboggan drawn by three dogs hitched tandem,
of the service as it now exists in the region between Sault Ste. Marie and
inaw, Mich.; a model of a United States postal car completely furnished;
of the German mail coach; a collection of United States mail bags, and
in use in this and other countries; a collection of postmarking stamps an
of the United States, dating from the year 1800.

Dead-Letter Office.—Collections of articles sent through the mails and for
to the Dead-Letter Office because misdirected or prohibited by postal la
this exhibit are included explosive bombs, deadly weapons, tarantulas and
snakes sent alive, and poisonous liquids and compounds. Other articles
ters written on collars, cuffs, and boards; children's toys, Indian scalps,
police billy, mail bag captured by Indians and smeared with the blood
murdered carrier. This collection contains a handkerchief taken from th
body of the United States postal clerk of the steamship *Oregon*, lost at
recovered one hundred and fourteen days afterwards, with other articles fr
mail of the ship. There is also a lock of the hair of Guiteau, the assassin
ident Garfield, sent through the mail by him while on trial.

Portraits.—This collection comprises an engraving of Benjamin Frank
first Postmaster-General of the American Colonies; portraits of the four P
ters-General from Tennessee, viz: Cave Johnson, under President Polk; A
Brown, under President Buchanan; David M. Key, and Horace Maynard
President Hayes; and a crayon of James A. Gary, present Postmaster-Gen

Postal records and letters, old and new.—These include the post-office le
Benjamin Franklin; the report of the committee of United States Senate J
20, 1829, on the transportation of the mails on Sunday; a postal card whic
eled around the world in one hundred and twenty days; history of the trav
registered letter in this and foreign countries; a religious book printed
obtained through the dead-letter office; statistics (framed) of the postal ser
the United States from 1775 to 1896, and a comparison of magnitude of the
service of the United States with France, Germany, and Great Britain.

As a part of the exhibit of this department, the post-office of the Centenni
has been established in the Government building.

THE DEPARTMENT OF THE INTERIOR.

This Department is represented by only four of its bureaus—Bureau of
tion, Bureau of Indian Affairs, the Patent Office, and United States Ge

Survey. These fill a floor space of about 4,000 square feet, and make an exhibit indicating the principal features of their work.

Bureau of Education.—[See report of the special agent.]

Bureau of Indian Affairs.—This Bureau attempts only to show its work in the Indian schools. Three large showcases, built by Indian pupils at the Indian school, Carlisle, Pa., contain articles of handicraft, such as carpenter and blacksmith work, shoemaking and tinware, embroidery, dresses, beadwork, etc. A large, three-seated wagon and several sets of harness are included in the display.

Patent Office.—This exhibit occupies the center of the square, and, as usual, exhibits models of American inventions. The models occupy ten large cases and are classified in groups, each showing the influence of the Patent Office in the development of some particular class of industry. Thus we find agricultural machinery, metal-working tools, typewriters, textile machines, woodworking machines, guns, measuring instruments, and machines for working clay, for excavating, for paper manufacture, etc., and a case of chemicals and dyestuffs derived from coal tar.

United States Geological Survey.—The Survey exhibits minerals, fossils in rocks, in considerable variety, with a series of sixteen relief maps and geological models. A wall 12 feet high and 48 feet long is covered with a display of geologic and topographic maps, and other wall space is used to display framed illustrations from publications of the Bureau. In four windows 32 large photographic transparencies are displayed, which not only illustrate American scenery, but also decorate the space assigned to this Department. Each transparency measures 36 by 28 inches.

THE DEPARTMENT OF JUSTICE.

The exhibit of the Department of Justice contains portraits of the eminent jurists who have been Attorneys-General. The photographs of the late Attorney-General Harmon and the present Attorney-General McKenna, as well as the associate justice and the circuit district judges of the sixth judicial circuit (to which circuit Tennessee is attached) are also shown, as well as a picture of the Supreme Court room at Washington.

The exhibit contains some of the publications issued by the Department and volumes of ancient law, interesting alike to the lawyer and student. It contains photographs of penal institutions throughout the country wherein are confined convicts sentenced by courts of the United States. Two cases are filled with articles made by inmates while undergoing imprisonment, such as embroidery, napkin rings, wax flowers, etc., and a teakettle made from a 10-cent piece.

Cases of blanks and forms illustrate the manner in which the business of the Department is transacted.

DEPARTMENT OF AGRICULTURE.

Weather Bureau.—The exhibit of this Bureau comprises a collection of instruments and apparatus for determining the velocity and recording the direction of the wind and clouds, various forms of barometers and apparatus illustrating their principles, rain and snow gauges, sunshine recorders, thermometers, etc.; a series of climatic charts, etc., containing specially prepared maps of miscellaneous meteorological data, large relief map showing the annual mean rainfall of the United States, etc.; framed photographs of Weather Bureau offices and special views, instruments, clouds, and lightning; samples of kites used in aerial investigations, with models of various forms, showing development, etc.

Bureau of Animal Industry.—This display consists of models and specimens in alcohol representing some of the infectious diseases in the domesticated animals, models of diseased horses' hoofs, shoes for the correction of faulty gaits, and the treatment of the diseases of the hoofs; tags, implements, etc., used in the United States meat inspection service; cultures of bacteria, toxins and antitoxins, animal parasites; a pyramid of wood samples from the Southern States; poultry, illustrating the gapeworm disease; photographs of famous horses and cows.

Biological Survey.—This section exhibits a number of characteristic Southern birds (mainly aquatic species) which have suffered most from the attacks of feather hunters, who kill the parents and leave the helpless young to die; various groups of birds that are beneficial by destroying insects or small animals; groups of animals mounted upon characteristic bases, among which are prairie dogs at the entrance of their burrows, ground squirrels from the prairie region of the Mississippi Valley, pouched gophers, etc.

Division of Entomology.—The most interesting features of this display are collections of insects affecting fruit trees, truck crops, forage plants, grains, live stock, etc., together with models in wax illustrating the injury caused by them;

a wax model of the cotton plant and models illustrating injury caused by the cotton worm, and the bollworm, with a number of the more important insecticides, with brief directions for their preparation and application; bromide enlargements of figures and photographs illustrating various important insects and field operations in the control of insects.

Division of Forestry.—The exhibit of this division comprises a monographic display of four commercially important timber trees of the South—longleaf pine, red cedar, white oak, and red gum; each species shown in a rustic monster frame formed of the timber of the species with bark on it, containing a map of geographical distribution, synonym and economic uses, photomicrophs (showing magnified structure of wood), botanical specimens, together with cross sections of young and old trunks and unfinished and finished wood showing characteristic appearance; representative forest botanical display of 140 Southern tree species mounted in glass boxes, each box specimen accompanied by a block of wood and a small map showing geographical distribution; three models of a farm showing (*a*) the destructive erosion consequent upon indiscriminate forest denudation; (*b*) the method of reclaiming the farm; (*c*) the model farm as reclaimed.

Division of Pomology.—Here are shown, among other things, models and water-color paintings of fruits adapted to cultivation in Tennessee and other Southern States; a collection of fruit descriptions illustrating methods used in recording varietal characteristics, for use in identification of varieties; living pineapple plant from Florida showing fruit in successive stages of development, and photographic enlargements illustrating methods of culture and marketing the same.

Division of Vegetable Physiology and Pathology.—This exhibit consists of collections of models, specimens, and photographs illustrating the habits of the different genera and species of edible and poisonous mushrooms and their cultivation. An interesting case contains models, photographs, specimens, and paintings, illustrating the characteristics of some of the more common plant diseases and the methods of laboratory and field work followed in the investigation of these diseases; also groups of bromide enlargements and maps showing field work in treating plant diseases and its results, and illustrating the distribution in the United States of the more common plant diseases.

Division of Agrostology.—This exhibit contains sixty sheaves of American grasses, chiefly Southern; eighty-four drawings of North American grasses, being originals of the illustrations for the "Handbook of North American Grasses," now in preparation, and two transparencies of grasses grown in Tennessee.

Office of Fiber Investigations.—This exhibit shows the commercial fibers of the United States, cultivated and imported. These are arranged in four cases of thirty-two panels, in series, to illustrate the raw fibers and their preparation, with examples of principal manufactures. The collections comprise flax, hemp, jute, cotton, ramie, sisal and manila hemps, Tampico, palmetto, cocoanut, and the principal species of brush fibers, such as piassava, palmyra, kittool, etc. Among fibrous substances are bamboo, rattan, straw plant, ramie, Southern cane fiber, silk cottons, and woody fibers. Among novelties are corn-pith cellulose, used for packing bulkheads of armored vessels, Cuba bast and willow and poplar shavings, used in millinary goods.

An interesting feature of the exhibit of the Department of Agriculture is a relief model of the State of Tennessee, treating of its topography and agricultural resources.

THE SMITHSONIAN INSTITUTION.

The exhibit of the Smithsonian Institution includes also the Bureau of American Ethnology, the National Zoological Park, the Bureau of International Exchanges, the Astro-Physical Observatory, and the United States National Museum. It is intended to convey a clear impression of the character and scope of the work accomplished by the institution and the bureaus under its direction.

A complete set of its publications, including those of the Bureau of Ethnology and National Museum, forms one of the principal features of this exhibit. There are portraits of James Smithson, the founder of the institution; three secretaries, Joseph Henry, Spencer Fullerton Baird, Samuel Pierpont Langley, and the late George Brown Goode, assistant secretary, so well and favorably known as a scientist and for his exposition work.

The Bureau of American Ethnology.—This exhibit consists of one-half of a Kiowa camping circle, with the associated shields and other objects, and is extremely interesting on account of the fact that this aboriginal tribe is now the only representative of a distinct stock of North American Indians.

The National Zoological Park.—This park is represented by a large model showing buildings, roadways, bridges, etc., while in the windows above are enlarged

photographic transparencies of objects of greatest interest in the park, including buffalo and other animals.

The Bureau of International Exchanges.—This Bureau is represented by a complete set of the publications of the United States Government for one year. Fifty similar sets are distributed annually by the Bureau to foreign countries. Numerous maps and diagrams, illustrating the workings of this Bureau, are also shown.

The Astro-Physical Observatory.—This exhibit consists of photographs of the exterior and interior of the building at Washington and of the principal instruments therein—siderostat, galvanometer, spectrometer, a bolometer or electric thermometer, the invention of Professor Langley, and large photographs of portions of the solar spectrum.

UNITED STATES NATIONAL MUSEUM.

The exhibit of the National Museum is larger than those of all other dependencies of the Smithsonian Institution combined. It has been intended, as far as possible, to show the scope of the Museum and to indicate the manner in which the collections at Washington are arranged, labeled, and displayed. It is divided into seventeen departments.

The Department of Mammals.—This exhibit comprises a collection of lemurs—monkey-like animals. About twenty-five species are artistically mounted, while on the walls are casts of the heads of the various species of porpoises and one of the smallest and rarest whalebone whales known to exist.

The Department of Birds.—This exhibit is one of the best ever shown by the Museum. It is placed near the main aisle and is notable for its excellent representation of the parrot family.

The Department of Reptiles and Batrachians.—This presents a group of the principal poisonous snakes of the United States, rattlesnakes and copperheads; tortoises are also shown.

The Department of Fishes.—This exhibit consists of a selected series of deep-sea fishes, supplemented by a number of casts of North American fishes, colored as in life.

The Department of Mollusks.—This exhibit represents the families of mollusks and brachiopods, and shows the utilization of the materials, such as pearl, cameo, etc., derived therefrom.

The Department of Insects.—This is most interesting, illustrating as it does protective resemblance and aggressive mimicry. Butterflies take on the color and appearance of the leaves upon which they most frequently settle. Aggressive mimicry of insects is shown by the imitation in form and color of twigs of trees and of insects known to be their enemies.

The Department of Marine Invertebrates.—The exhibit of this department comprises sponges, corals, and echinoderms. Suspended from the ceiling are life-size models, one of the giant squid and one of the octopus or devil-fish, made familiar to everyone by Victor Hugo's Toilers of the Sea.

The Department of Comparative Anatomy.—This exhibit includes two series of specimens, one showing the modification of the limbs of animals for different modes of life and the other the structure of the human brain.

The Department of Paleontology.—This department is represented by a collection of fossils from ancient bothrioepis to modern bony fish, like the shad, and by synoptic collections of trilobites and crinoids.

The Department of Geology.—A collection from this department illustrates in a most striking way the occurrence and association of gold and silver in nature.

The Department of Minerals.—This instructive exhibit contains about five hundred specimens of selected minerals.

The Department of Ethnology.—This interesting display comprises groups depicting the home life and arts of the Pueblo Indians. A prominent feature of the exhibit is a hut occupied by Norton Sound Eskimos. Fine and extensive collections of dance masks and types of basketry used by the Indians of the Pacific coast are included, as are also specimens of Pueblo pottery and implements for weaving.

The Department of Prehistoric Anthropology.—This department is represented by implements and objects used by prehistoric man at all epochs and periods. The State of Tennessee being rich in implements and articles belonging to prehistoric man, the field of American archæology was left entirely to the local archæologists and private exhibitors, and the entire display of this department is confined to specimens from foreign countries and is about equally divided between the stone and bronze ages.

The Department of Oriental Antiquities.—The display from this department consists of objects illustrating Brahminism and Buddhism, the principal religions of

eastern Asia; Mohammedanism, the literary history of the Bible, and the re
ceremonies of the Jews.

The Department of Technology.—The collections selected for this exhibit
of objects illustrating the early methods of transportation in the Southern
a series of models from the primitive sledge to the introduction of the first r
in the United States, which ran in South Carolina in 1831. There is a mod
full-rigged ship with the various sails, ropes, spars, etc., in place and labele
400 in number, and an accurate and authentic rigged model of the *Savann*
first steamship to cross the Atlantic.

From the electrical collections of the Museum there is displayed a series
senting the early instruments of Franklin, Henry, Morse, Vail, and Page.

Historical section.—Numerous historical objects, coins, and medals, illust
American history, form a prominent feature of the Museum exhibit.

Materia medica.—This section is represented by instructive specimens
ural and cultivated cinchona barks and their products and the alkaloids of

Numerous transparencies—photographs on glass—illustrating particul
tures of the exhibits are placed in the windows.

The National Museum has an interesting ethnological collection of exclu
woman's work among the aborigines displayed in the Woman's Building, a
a portion of the lace collection belonging to Dr. Thomas Wilson.

UNITED STATES FISH COMMISSION.

The exhibit of the United States Fish Commission is located in the sou
corner of the Government building and occupies 5,000 square feet of space
form of an L. It is arranged to show the character of the work performed b
of the divisions of the Commission, the method and apparatus employe
results attained, and is classified under three heads—scientific inquiry, fi
ture, and methods and statistics of the fisheries.

In the section of scientific inquiry are to be found models and illustrat
the vessels of the Commission, specimens of the nets, dredges and other coll
apparatus for scraping the ocean bottom, apparatus used in assorting and p
ing the collections, a model of the sounding machine used in deep-sea wor
samples of the various thermometers used in physical observations. The re
the scientific inquiry explorations of the Commission appear in the form of
besides specimens of corals, crabs, star-fishes, sea-urchins, and various i
brate animals; also extensive series of oysters, showing the rate of grov
different bottoms, and the method of attachment of the spat and the i
produced by starfish, drills, and other enemies of the oyster.

Another interesting exhibit included in this section consists of 150 flexibl
of fishes painted from the fresh or living specimens in faithful imitation of
Two groups of sea lions and fur seals are part of this section.

The methods employed by the fisheries of the South Atlantic, Gulf, and
sippi States are illustrated by models of pound nets, seines, spars, hooks, t
etc. A series of models of vessels shows the development of the fishing ve
the present day from the crude craft first used in this country. The v
phases of fishing life are illustrated by photographs.

In the fish-culture section an effort is made to show in a practical w
methods followed in hatching the eggs of salmonidæ, representing heavy
shad, representing the semibuoyant types, and cod, representing the floating
eggs. Supplies of shad eggs will be delivered weekly until June 10 from
ington and hatched at the east entrance of the grotto. The hatch will be
ated in the Cumberland River. Trout eggs are furnished from the stre
Colorado, and the fish resulting from the same will be in the aquarium duri
exposition.

The aquarium, located in the southeast corner of the building, is a grot
L-shaped structure, 120 feet long, and contains twenty-two tanks. Each
7 feet long, 3 feet high, and 5 feet wide at the top. An equal number of ta
salt water and fresh water, respectively, are arranged on each side of the
with a passageway 12 feet wide dividing them.

The tanks next to the wall contain many of the food-fishes propagated
Commission, besides a large number of the important food and economic
of the Mississippi River Valley and from the States bordering on the Gu
Atlantic coasts. In the other tanks are shown most of the important fishes
Gulf, including the snappers, groupers, pompano, crevalle, and mullet, al
bright-colored tropical fishes, crustaceans, shellfish, etc.

The water for displaying the marine fishes was brought from Morehead
N. C., in tank cars, and is stored in a large reservoir tank beneath the floor.
this tank it is forced, by means of nickel pumps driven by electricity,

smaller tank 18 feet above the floor, located in the southeast corner of the building. It is introduced into the aquarium from the overhead tank by means of gravity. From the aquaria it returns to the reservoir, first passing through a filter, which removes all extraneous matter. As an aid in keeping this water pure, air is being constantly forced into it by means of an air pump, operated by hydraulic pressure. The air is liberated in minute particles at the bottom of the tanks through plugs of basswood inserted in rubber liberator holders attached to rubber tubing, which is connected with a pipe leading from an air-pressure tank.

The fresh water is obtained from an artesian well 84 feet deep, located near the southeast corner of the building, which supplies a constant stream of clear cold water of 58 degrees temperature. Connections have also been made with the city waterworks, so that in case of failure from the well, the aquarium can be maintained in that way. The overflow from the fresh-water aquarium passes into Lake Katherine.

The interior of the grotto is finished in adamant and cement, partly as stucco work and partly plastered, in imitation of a roughly blasted rock tunnel. Where the two arms of the L meet, a rotunda has been formed, with a pool at one side in imitation of an entrance to a water cave. It is illuminated by electric lights. Here and there in the grotto, mosses, ferns, and other evergreens are planted in the rockwork. Two arched portals in imitation of cut stone and of simple architectural design form the entrance to the grotto.

The aquaria tanks are lighted from the rear, and a number of ventilators are placed at the crown of the grotto arch. The rockwork of the interior of the grotto is in imitation of light trap rock; that of the portals of cream-colored limestone, with trimmings in darker shades.

Table exhibited as a wall chart at the Tennessee Centennial.

[Progress in twenty years of education in the South, comprising the States of Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, Texas, Mississippi, Louisiana, Arkansas, and Missouri.]

Professors and instructors	1,602	2,150	3,096
Students	13,014	19,987	26,774

The population was about one-half greater in 1895 than in 1875.

In the public schools the number of pupils was over two and one-half times as great; teachers were nearly twice as numerous, females having increased far more rapidly than males. There were nearly twice as many schoolhouses, and school property was over three and one-fourth times as valuable. The average school term was twelve days longer, and the total expenditure was over two and one-fourth times as much.

Ninety-six new colleges were established between 1875 and 1895; there were 1,494 more professors and over twice as many students at the latter date as at the former.

THE EXPOSITION AND ITS STRUCTURES.

Reprinted from an account by Robert A. Halley in the Nashville American, May 1, 1

The site of the exposition could not be more favorably located, and, i there was no other location which could have been so improved by the expen of a similar amount of money. Including West Side Park and adjacent pro there are about 200 acres available, and the greater part of this is occup one way or another. Less than 2 miles from the public square, which acknowledged center of the city, it is sufficiently elevated to command a fin of the entire western portion of the city and the outlying suburb to the nor and southwest of the city of Nashville. In the distance the State capitol up in its grandeur and the entire aspect is one that is intensely pleasing to t

THE SITE.

When the exposition people took charge they found a park with hundr trees well kept, and to these they have added hundreds more, which no their shade to the visitor and suggest the delightful evenings to be spent them the coming summer nights. The beautiful blue grass covers ever which would otherwise be vacant, and through the green borders wind cha shaded avenues and walkways. Flowers are everywhere, in beds, in mas banks, or single plants throw up their heads proudly wherever there is a spot or a pretty view. Orange trees and lemon trees show their golden or fruits, and the palms of the Tropics rear their stately tufts of dark green f Cacti fill beds in the sunny corners, and here and there all the summer lon be blooms of that strange barbaric beauty and brightness that characteriz wonderful children of the desert. Scarlet geraniums, multitinted coleu fiery nasturtiums lend their glow and color to the beautiful outdoor dec scheme. Through the quiet waters of the lakes glide the gondolas of V steered by the sons of the sunny land where their picturesque garb may b at home, but where it can not lend a more artistic beauty to the land Arbors of native vines, and one arbor where only the strange tropical vines gourd family grow, offer a cool and shaded retreat to those whose feet have the walks of the exposition till they tire from the very surfeit of delight. the trees and in the arbors the sultry heat of the summer may not reac spring and autumn lend added beauty to the prospect when seen throu green curtains of the vines.

MINERALS AND FORESTRY BUILDING.

The first building to greet the eye after the visitor has fully admired th pect and starts on his tour of the displays is that known as the minera forestry building. It stands on the space between the northern shore of Katharine and the southern extremity of Lake Watauga. It is not only nent, but handsome and commodious. It belongs to the Doric order of ar ture as modified by the Romans when they had attained their highest exce in the art of building. Its size is 526 by 124 feet, with an annex 72 by 16 Its main entrances are three in number and each is marked by an imposin tico with six columns. This gives the building a pleasing general effect. columns guarding the entrances are crowned by sculptural gables in high and of beautifully appropriate designs.

The minerals and forestry building is filled with the products of the mi forest, and includes every variety of materials used for building a home, fr humblest cabin to the palace. Not only the marbles, the stones, the cla minerals, the coals, the ores, the precious metals, and the woods of Tennesse the vast number of their varied products in all branches of industrial art, th be shown, but there will be some of the finest products of other States in th lines. Georgia has a magnificent exhibit of her products in minerals ar estry, and other States have made valuable contributions to the same work. structures inside the building are of particular interest—the cabin built o shall County cedar logs taken from a structure which stood for over eighty and the reproduction of the Ann Hathaway cottage, to be used as Ha County's headquarters. The State's display is particularly fine.

THE AUDITORIUM.

West of the minerals and forestry building stands the auditorium, wh big concerts and conventions will have possession during the exposition. V seating capacity of 6,000, it is deemed ample for all gatherings except on

occasions. Colonial in style and Ionic in treatment, its airy porticos, facing the points of the compass, give the building the shape of a short cross, except for the colonnades extending from the main entrance around in either direction to the ends of the building. Above the colonnades are balconies from which immense numbers of people may view the fireworks at night or the pageants of the day. From the tower, 100 feet above the roof, can be had a view of the electrical effects at night, which will not be equaled by any other view on the grounds. In the day from this tower can be had a fine view, not only of the exposition, but of the city of Nashville farther away. The inside finish is of hard wood, and a broad gallery extends around three sides of the hall. The stage and band pit are of ample dimensions, even for the great bands engaged and for the great conventions booked for holding there this summer.

THE GOVERNMENT BUILDING.

In the southern part of the grounds is situated the splendid Government building, 350 by 150 feet in extent, and in the form of a cross. The surmounting dome is 50 feet high and very similar to the dome on the new Congressional Library in Washington. The Government has not been niggardly in supplying the ways and means whereby this great public undertaking may be aided, and not only appropriated the sum of $130,000 for the building and exhibit, but has done more. By act of Congress it provided for the free admission of foreign exhibits intended for exhibition, and this information was transmitted to every foreign Government with an invitation to participate in the exposition. It is needless to say that this building and its varied exhibits will be one of the most interesting and valuable features of the entire exposition. The displays will be on an elaborate scale, and commissioners connected with past expositions have been appointed from every department, so that the advantage of their experience may be had in this instance. The exhibits represent every working department and all will be educational in their nature. The fisheries display, of course, will be the leading attraction to most people, but the models of guns, ships, etc., and the displays of important papers, the show of army costumes from the beginning, and thousands of other objects are worthy of anybody's inspection.

THE WOMAN'S BUILDING.

The woman's building illustrates what woman has accomplished in the past hundred years. The pioneer's cabin of logs near at hand, with spinning wheel, hand loom, and all the early implements with which women of that day did their work, stands as a forcible comparison between the women of then and the women of now. Every appliance of modern art, every convenience for the home, and every decorative idea for the advancement of the higher tastes will be found in the splendid palace which the Exposition management has reared to perpetuate the high regard of Tennesseeans for woman. The Woman's Building is modeled a little after the Hermitage, and some pleasing features of the Grecian architecture have been added with fine effect. The building is 160 by 65 feet, and eight massive columns support the roof, which is surmounted by an observatory. A flight of steps of pink Tennessee marble lead to the entrance. The surroundings are most beautiful, including the splendid Moretti fountain, the three other fountains, besides one in the main hall. Of the interior of the building much might be said without giving an adequate idea of its beauty. The assembly room, decorated by the Knoxville women, will be the meeting place of the many women's conventions arranged for during May and October. There is a parlor for the president, Mrs. Kirkman, elegantly furnished by the contributions of women of the State. There is the magnificent main hall, furnished and decorated by the Memphis women; the red-cedar room, decorated by the Murfreesboro women, where relics of the three Presidents, Jackson, Polk and Johnson, will be seen; Chattanooga room, Georgia room, New York room, Mount Vernon room, Colonial bedroom, Oriental room, model kitchen, where demonstrations in cooking will be given free during the summer, a display of laces of the world, a vast collection of the art works of women in every branch of decorative and applied art; a library of the books written by women, the room where the patents and inventions of women are shown, the salesroom, where articles for sale are kept, and a number of others. All are beautifully decorated and furnished. The halls are full of displays from the counties, and many other things are to be seen.

COMMERCE BUILDING.

Commerce and agriculture are the two words which appear on the seal of the State of Tennessee and the two leading exhibit buildings were therefore very appropriately named thus. The commerce building is the largest structure on the

the improvement of transportation facilities and what was done in the initial stages of the railroad era. The De Witt Clinton train, the first, will stand side by side with the modern locomotive and its train of elegant vestibule cars. Vehicles of every variety will be shown in their most splendid finish.

AGRICULTURE BUILDING.

The products of the soil of Tennessee will be exhibited in the agriculture building, by many considered the gem of the entire exposition group. The Renaissance style of architecture has been used, and the dimensions are 525 feet by 200 feet. The central dome rises 100 feet, while six minor domes lend a charm to the whole which can not be described. Four entrances lead under arches with statuary. The classic lines and beautiful proportions can be seen from almost every part of the grounds to advantage, and at night the building is particularly adapted for an electrical display. The interior decorations of this building have been pronounced superior to anything ever seen before in the history of expositions, surpassing, according to Chicago people themselves, the best seen at the World's Fair. Within will be the vast and varied productions of Tennessee and agricultural implements, still and in motion, from nearly every first-class factory of the country. The decorations made from field products are especially fine, and each of the small domes is decorated with a single product, one in corn, one in tobacco, one in cotton, and one in grain.

MACHINERY BUILDING.

In the machinery building utility and beauty are united, satisfying the artistic tastes and practical demands at the same time. The building is 375 by 138 feet, and in outline and detail it satisfies the most fastidious tastes in architectural art. There is no steam admitted, that being supplied from the power house, some distance away. This will keep the building pleasant on warm days, and enable visitors to see it without discomfort. The various machines in operation in this building will manufacture a number of things of interest, and one of these working exhibits will be a ribbon-weaving loom. The great engines moving noiselessly will be no small part of the interest, as there are some of the finest here that were ever made.

NEGRO BUILDING.

The negro building, which many think the most beautiful on the ground, not only in situation but in design, is one of the finest evidences that could be given of the feelings of the white men of the South for their former slaves. The negroes of Tennessee have the opportunity of their lives to make this display educational in the highest sense, and this they are doing every day. The building was not completed in time for the entire exhibits to be arranged, but since it was turned over the negro department has done great work in getting it stocked with the many fine exhibits which they had gathered from every part of the State and the South. The sight of the building across the fair Lake Watauga is no more beautiful than the displays within, for the outside of the structure can not tell the story that is told by the interior. That story is the story of the negro race from the days of slavery to the present—the story of achievement under obstacles often seemingly impossible to overcome. The school exhibits and the exhibits showing the life of some of the graduates after their school days closed and real life began are of notable interest.

HYGIENE AND EDUCATION.

The hygiene and educational building was really an outgrowth of the increasing size of the exposition. The space assigned these two departments was so soon filled that the need of greater accommodation early made itself felt. The final result was the erection of this structure, and not only has the space been taken up, but the gallery of the commerce building has been taken as an annex to the educational department. The building is in the Renaissance style, and is 144 feet square. A peculiarity is that the four sides are identical in finish, and the only difference to be noted is that on the south side there will be two groups of statuary, representing oratory and philosophy. Inside the educational department will be seen the finest and most complete collection of school work ever shown at an exposition anywhere. This will include all work done by schools of and above the grade of colleges. The lower schools will place there work in the children's building. In the hygiene department will be grouped one of the most

THE FLAGPOLE.

The flagpole is the cause of more questions than anything else on the grounds, because it is invariably asked: "How tall is it?" It is 285 feet, and the pole itself represents Tennessee. There are fifteen columns around the pavilion at the base, each of a different Tennessee wood. These represent the fifteen States that preceded Tennessee into the Union. The sixteenth, the flagpole, is Tennessee.

THE PYTHIAN BUILDING.

The Knights of Pythias have one of the prettiest headquarters ever built at any exposition. In it there will be reading rooms, resting rooms, and all the comforts of a home to be enjoyed by members of this order and their families who come to the exposition.

THE PALACE CAR.

The Seaboard Air Line Palace Car is one thing which is there for a purpose. It is the headquarters of all the towns and cities on the line of that road, and in it about every ten days some one of the cities will be the host and give a banquet which will be attended by citizens of that place and by invited guests.

THE JUNIOR ORDER BUILDING.

The Junior Order of United American Mechanics have a pretty building to the south of the wigwam and will have everything there for the comfort and entertainment of their members.

The Cotton Belt Line has a neat pavilion near the Transportation Building for their exhibits.

The photograph gallery is both attractive and useful, and worth a visit from any one who wants a good picture.

KNOXVILLE BUILDING.

Capitol avenue is a thoroughfare which has been laid out but a short time, but six very handsome structures are either up or nearing completion. The largest of these is the Knoxville Building, in which that prosperous city will have headquarters and which will be filled with Knoxville exhibits. It is nearly complete and will be a most interesting place to visit.

ILLINOIS BUILDING.

At the far end of the avenue is the fair white Illinois Building, the reproduction of the Administration Building at the World's Fair, where the great State of Illinois and the great city of Chicago will do the honors during the exposition. The forty-eight statues which ornament this building are like those on the Administration Building at Chicago, and cost over $1,000 dollars each to model. The same models were used for these.

CINCINNATI BUILDING.

Directly opposite Knoxville Building is the Cincinnati Building, the first to be commenced on the avenue, and it is now about ready for dedication. The people of Cincinnati have from the first taken an interest in this exposition, and as soon as they became satisfied that the exposition was going to be a success they went to work and raised the money for this building.

NEW YORK BUILDING.

New York State is about finishing up a building that will be very delightful to all visitors. It is commodious and well planned, and the interior decorations are in keeping with the character of the structure. The building cost a large amount and will be the center of many pleasant times before the exposition closes.

LOUISVILLE BUILDING.

Louisville is erecting a building the design for which shows the beauty of the idea carried out, and here will be another place where social pleasure will abound. The building will be the rallying place for all Louisville people and for Kentuckians as well, and the close relations between the States will be closer than ever before the show is over.

THE PRESS BUILDING.

The press of the country has been kind to the exposition, and the management has remembered them by erecting for the newspaper men a commodious and convenient place where they may work or rest. The building is of the prettiest design and is now about finished.

CHAPTER XXII.

EDUCATIONAL DIRECTORY.[1]

I.—Chief State School Officers.

Name.	Address.	Official designation.
John O. Turner	Montgomery, Ala	State superintendent of education.
Sheldon Jackson	Sitka, Alaska	General agent of education.
A. P. Shewman	Phœnix, Ariz	Superintendent of public instruction.
Junius Jordan	Little Rock, Ark	State superintendent of public instruction.
Samuel T. Black	Sacramento, Cal	Do.
Miss Grace E. Patton	Denver, Colo	Do.
C. D. Hine	Hartford, Conn	Secretary of State board of education.
	Dover, Del	Do.
W. B. Powell	Washington, D. C	Superintendent of District schools.
W. N. Sheats	Tallahassee, Fla	State superintendent of public instruction.
Gustavus R. Glenn	Atlanta, Ga	State school commissioner.
L. N. B. Anderson	Boise, Idaho	State superintendent of public instruction.
Samuel M. Inglis	Springfield, Ill	Do.
D. M. Geeting	Indianapolis, Ind	Do.
R. C. Barrett	Des Moines, Iowa	Do.
William Stryker	Topeka, Kans	Do.
W. J. Davidson	Frankfort, Ky	Do.
J. V. Calhoun	Baton Rouge, La	State superintendent of education.
W. W. Stetson	Augusta, Me	State superintendent of public schools.
E. B. Prettyman	Baltimore, Md	Secretary of State board of education.
Frank A. Hill	Boston, Mass	Do.
Jason E. Hammond	Lansing, Mich	State superintendent of public instruction.
W. W. Pendergast	St. Paul, Minn	Do.
A. A. Kincannon	Jackson, Miss	State superintendent of education.
John R. Kirk	Jefferson City, Mo	State superintendent of public schools.
E. A. Carleton	Helena, Mont	State superintendent of public instruction.
W. R. Jackson	Lincoln, Nebr	Do.
H. C. Cutting	Carson, Nev	Do.
Fred. Gowing	Concord, N. H	Do.
Chas. J. Baxter	Trenton, N. J	Do.
Placido Sandoval	Santa Fe, N. Mex	Superintendent of public instruction.
Charles R. Skinner	Albany, N. Y	State superintendent of public instruction.
C. H. Mebane	Raleigh, N. C	Do.
J. G. Holland	Bismarck, N. Dak	Do.
Oscar T. Corson	Columbus, Ohio	State commissioner of common schools.
S. N. Hopkins	Guthrie, Okla	Superintendent of public instruction.
G. M. Irwin	Salem, Oreg	State superintendent of public instruction.
Nathan C. Schaeffer	Harrisburg, Pa	Do.
Thomas B. Stockwell	Providence, R. I	Commissioner of public schools.
W. D. Mayfield	Columbia, S. C	State superintendent of education.
Frank Crane	Pierre, S. Dak	State superintendent of public instruction.
Price Thomas	Nashville, Tenn	State superintendent of public instruction.
